8 A probabilistic argument on the distribution of $|g^{-1}(n)|$

8.1 Definitions and preliminaries

Recall from the introduction that we define the Dirichlet invertible function $g(n) := \omega(n) + 1$ and denote its inverse with respect to Dirichlet convolution by $g^{-1}(n) = (\omega + 1)^{-1}(n)$. We can compute the Dirichlet inverse of $g(n)$ exactly for the first few sequence values as (see Table T.1 of the appendix section)

$$\{g^{-1}(n)\}_{n\geqslant 1} = \{1, -2, -2, 2, -2, 5, -2, -2, 2, 5, -2, -7, -2, 5, 5, 2, -2, -7, -2, -7, 5, 5, -2, 9, \ldots\}.$$

The sign of these terms is given by $\operatorname{sgn}(g^{-1}(n)) = \frac{g^{-1}(n)}{|g^{-1}(n)|} = \lambda(n)$. This useful property is inherited from the distinctly additive nature of the component function $\omega(n)$.

There does not appear to be an easy, nor subtle direct recursion between the distinct values of $g^{-1}(n)$, except through auxiliary function sequences. However, the distribution of distinct sets of prime exponents is fairly regular so that $\omega(n)$ and $\Omega(n)$ play a crucial role in the repitition of common values of $g^{-1}(n)$. The following observation is suggestive of the quasi-periodicity of the distribution of distinct values of $g^{-1}(n)$ over $n \geqslant 2$:

Heuristic 8.1 (Symmetry in $g^{-1}(n)$ in the exponents in the prime factorization of n)**.** Suppose that $n_1, n_2 \geqslant 2$ are such that their factorizations into distinct primes are given by $n_1 = p_1^{\alpha_1} \cdots p_r^{\alpha_r}$ and $n_2 = q_1^{\beta_1} \cdots q_r^{\beta_r}$ for some $r \geqslant 1$. If $\{\alpha_1, \ldots, \alpha_r\} \equiv \{\beta_1, \ldots, \beta_r\}$ as multisets of prime exponents, then $g^{-1}(n_1) = g^{-1}(n_2)$. For example, g^{-1} has the same values on the squarefree integers with exactly two, three, and so on prime factors (compare with the numerical data in Table T.1 starting on page 47).

Conjecture 8.2. *We have the following properties characterizing the Dirichlet inverse function $g^{-1}(n)$:*

- ***(A)*** $g^{-1}(1) = 1$*;*
- ***(B)*** *For all $n \geqslant 1$, $\operatorname{sgn}(g^{-1}(n)) = \lambda(n)$;*
- ***(C)*** *For all squarefree integers $n \geqslant 1$, we have that*

$$|g^{-1}(n)| = \sum_{m=0}^{\omega(n)} \binom{\omega(n)}{m} \cdot m!.$$

We illustrate parts (B)–(C) of the conjecture clearly using Table T.1. The realization that the beautiful and remarkably simple combinatorial form of property (C) in Conjecture 8.2 holds for all squarefree $n \geqslant 1$ motivates our pursuit of simpler formulas for the inverse functions $g^{-1}(n)$ expressed by sums of auxiliary sequences of arithmetic functions.

For natural numbers $n \geqslant 1, k \geqslant 0$, let

$$C_k(n) := \begin{cases} \varepsilon(n) = \delta_{n,1}, & \text{if } k = 0; \\ \sum\limits_{d|n} \omega(d) C_{k-1}(n/d), & \text{if } k \geqslant 1. \end{cases}$$

For any $n \geqslant 1$, we can prove that (see Lemma 6.3)

$$g^{-1}(n) = \lambda(n) \times \sum_{d|n} \mu^2\left(\frac{n}{d}\right) C_{\Omega(d)}(d). \tag{45}$$

8.2 Our forms of generalizations to Erdös-Kac for additive functions

We want to actually quantify how precise our intuition in the previous subsection is with respect to the observation that since $|g^{-1}(n)|$ depends so closely on $\omega(n)$, it should similarly behave regularly, and of course not deviate too far from its average order on the set $n \leqslant x$ as $x \to \infty$. More generally, we obtain limiting normal-variant distributions for the densities of key arithmetic functions within bounded ranges.

The proof of Theorem 8.3 closely parallels the argument for an Erdös-Kac theorem for the function $\Omega(n)$ from [8, §7.4]. We utilize this result to prove a limiting distribution-like property for the densities of $|g^{-1}(n)| - \mathbb{E}|g^{-1}(n)|$ in Corollary 8.4. This result, in particular, offers a new take on bounding the summatory functions $G^{-1}(x)$ from the previous section.

In what follows, let

$$\mu_x(C) := \frac{\pi^2}{6}\log\log x, \sigma_x(C) := \sqrt{\mu_x(C)}, \widehat{c} := \frac{1}{6} \times \prod_{p>2}\left(1 - \frac{1}{(p-1)^2}\right)^{-1} \approx 1.5147.$$

For any $z \in \mathbb{R}$, we use the standard notation $\Phi(z) := \frac{1}{\sqrt{2\pi}}\int_{-\infty}^{z} e^{-t^2/2}dt$.

Theorem 8.3 (Central limit theorem I)**.** *Let $Y > 0$ and $z \in [-Y, Y]$. Then*

$$\frac{1}{x} \cdot \#\left\{2 \leqslant n \leqslant x : \frac{\lambda(n)(-1)^{\omega(n)}C_{\Omega(n)}(n) - \mu_x(C)}{\sigma_x(C)} \leqslant z\right\} = \frac{\widehat{c}}{(\log x)^{1-\zeta(2)}} \cdot \Phi(z) + o(1),$$

uniformly for all $-Y \leqslant z \leqslant Y$ as $x \to \infty$.

Corollary 8.4 (Central limit theorem II)**.** *Let $Y > 0$ and $z \in [-Y, Y]$. Set the auxiliary variable*

$$w_x(z) := \frac{\pi^2}{6} \cdot |z + \mu_x(C)|.$$

Then

$$\frac{1}{x} \cdot \#\left\{2 \leqslant n \leqslant x : \frac{|g^{-1}(n)| - \mathbb{E}|g^{-1}(n)|}{\sigma_x(C)} \leqslant z\right\} = \frac{\widehat{c}}{(\log x)^{1-\zeta(2)}}\left[\Phi\left(w_x(z)\right) - \Phi\left(-w_x(z)\right)\right] + o(1),$$

uniformly for all $-Y \leqslant z \leqslant Y$ as $x \to \infty$.

8.3 Proofs of the main theorems

Proposition 8.5. *For $|z| < 2$, let the summatory function be defined as*

$$\widehat{A}_z(x) := \sum_{n \leqslant x} (-1)^{\omega(n)} C_{\Omega(n)}(n) z^{\Omega(n)}.$$

Then

$$\widehat{A}_z(x) \sim \frac{x \cdot F(2, z)}{\Gamma(z)}(\log x)^{z-1},$$

where the function $F(s, z)$ is defined for $\mathrm{Re}(s) > 1$ in terms of the exponential of the prime zeta function by

$$F(s, z) := \exp\left(z \cdot P(s)\right) \times \prod_p \left(1 - \frac{1}{p^s}\right)^z.$$

Proof. We know from the proof of Proposition 4.1 that for $n \geqslant 2$

$$C_{\Omega(n)}(n) = (\Omega(n))! \times \prod_{p^\alpha || n} \frac{1}{\alpha!}.$$

Then we can generate the denominator terms by the Dirichlet series

$$\sum_{n \geqslant 1} \frac{C_{\Omega(n)}(n)}{(\Omega(n))!} \cdot \frac{(-1)^{\omega(n)} z^{\Omega(n)}}{n^s} = \prod_p \left(1 + \sum_{r \geqslant 1} \frac{z^{\Omega(p^r)}}{r! \cdot p^{rs}}\right)^{-1} = \exp\left(z \cdot P(s)\right).$$

So by computing a Laplace transform on the right-hand-side of the above with respect to the variable z, we obtain

$$\sum_{n\geqslant 1} C_{\Omega(n)}(n) \cdot \frac{(-1)^{\omega(n)} z^{\Omega(n)}}{n^s} = \int_0^{\infty} e^{-t} \exp\left(tz \cdot P(s)\right) dt = \frac{1}{1-P(s)z}.$$

It follows that

$$\sum_{n\geqslant 1} \frac{(-1)^{\omega(n)} C_{\Omega(n)}(n) z^{\Omega(n)}}{n^s} = \zeta(s)^z \times F(s,z),$$

where

$$F(s,z) := \frac{1}{1-P(s)z} \times \prod_p \left(1-\frac{1}{p^s}\right)^z, \mathrm{Re}(s) > 1, |z| \leqslant R < 2.$$

Note that we are unable to sum this result in exactly the same format as in the reference [8, §7.4; Thm. 7.18] by effectively setting $s := 1$. However, since for any $|z| \leqslant R < 2$ we have that

$$\left| \sum_{n\geqslant 1} \frac{(-1)^{\omega(n)} C_{\Omega(n)}(n) z^{\Omega(n)}}{n^2} \right| < +\infty,$$

we will adapt the details to the traditional case where this method arises in the reference application so that we can sum over our modified function depending on $\Omega(n)$. In fact, we notice that since $|z|^{\Omega(n)} \leqslant n$, we have the exact DGF

$$\mathcal{H}(s) := \sum_{n\geqslant 1} \frac{\lambda(n) C_{\Omega(n)}(n)}{n^s},$$

which is absolutely convergent for $\mathrm{Re}(s) > 1$. The DGF $\mathcal{H}(s)$ is thus an analytic function of s whenever $\mathrm{Re}(s) > 1$, and so we can differentiate it any integer $m \geqslant 0$ number of times to still obtain an absolutely convergent series of the form

$$\left| \sum_{n\geqslant 1} \frac{(-1)^{\omega(n)} C_{\Omega(n)}(n) (\log n)^m z^{\Omega(n)}}{n^s} \right| < +\infty, \mathrm{Re}(s) > 2.$$

Let the function $d_z(n)$ have DGF $\zeta(s)^z$ for $\mathrm{Re}(s) > 1$, with corresponding summatory function $D_z(x) := \sum_{n\leqslant x} d_z(n)$. Furthermore, adopting the notation from the reference, we set $b_z(n) := (-1)^{\omega(n)} C_{\Omega(n)}(n) z^{\Omega(n)}$, let the convolution $a_z(n) := \sum_{d|n} b_z(d) d_z(n/d)$, and let the summatory function $A_z(x) := \sum_{n\leqslant x} a_z(n)$. Then we have that

$$\begin{aligned} A_z(x) &= \sum_{m\leqslant x/2} b_z(m) D_z(x/m) + \sum_{x/2<m\leqslant x} b_z(m) \\ &= \frac{x}{\Gamma(z)} \times \sum_{m\leqslant x/2} \frac{b_z(m)}{m^2} \log\left(\frac{x}{m}\right)^{z-1} + O\left(x \sum_{m\leqslant x} \frac{|b_z(m)|}{m^2} \times \log\left(\frac{2x}{m}\right)^{\mathrm{Re}(z)-2}\right). \end{aligned}$$

The error term in the previous equation satisfies

$$\begin{aligned} x \sum_{m\leqslant x} \frac{|b_z(m)|}{m^2} \times \log\left(\frac{2x}{m}\right)^{\mathrm{Re}(z)-2} &\ll x(\log x)^{\mathrm{Re}(z)-2} \sum_{m\leqslant\sqrt{x}} \frac{|b_z(m)|}{m^2} + x(\log x)^{-(R+2)} \sum_{m>\sqrt{x}} \frac{|b_z(m)|}{m^2} (\log m)^{2R} \\ &\ll x(\log x)^{\mathrm{Re}(z)-2}. \end{aligned}$$

In the main term estimate for $A_z(x)$, when $m \leqslant \sqrt{x}$

$$\log\left(\frac{x}{m}\right)^{z-1} = (\log x)^{z-1} + O\left((\log m)(\log x)^{\mathrm{Re}(z)-2}\right).$$

Hence, the main term sum over the interval $m \leqslant x/2$ corresponds to bounding

$$\begin{aligned}\sum_{m \leqslant x/2} b_z(m) D_z(x/m) &= x(\log x)^{z-1} \sum_{m \leqslant x/2} \frac{b_z(m)}{m^2} \\ &\quad + O\left(x(\log x)^{\mathrm{Re}(z)-2} \sum_{m \leqslant \sqrt{x}} \frac{|b_z(m)|}{m^2} + x(\log x)^{R-1} \sum_{m > \sqrt{x}} \frac{|b_z(m)|}{m^2}\right) \\ &= x(\log x)^{z-1} F(2,z) + O\left(x(\log x)^{\mathrm{Re}(z)-2} \sum_{m \geqslant 1} \frac{b_z(m)(\log m)^{2R+1}}{m^2}\right).\end{aligned}$$

This yields the asymptotic main term on the bound cited above. □

Theorem 8.6. *We have uniformly for* $\log\log x - (\log\log x)^{2/3} \leqslant k < 2\log\log x$ *as* $x \to \infty$

$$\widehat{C}_k(x) := \sum_{\substack{n \leqslant x \\ \Omega(n)=k}} \lambda(n)(-1)^{\omega(n)} C_k(n) \asymp \frac{\hat{c} \cdot x}{6 \cdot \log x} \cdot \frac{\zeta(2)^{k-1} \cdot (\log\log x)^{k-1}}{(k-1)!}.$$

Moreover, for sufficiently large x we have that

$$\left|\sum_{n \leqslant x} \lambda(n)(-1)^{\omega(n)} C_{\Omega(n)}(n)\right| \asymp \frac{\hat{c}}{\sqrt{2}\pi^{5/2}} \cdot \frac{x(\log x)^{2\log\pi - \frac{\log 2}{2} - \log 3}}{\sqrt{\log\log x}},$$

where the constant power is approximated by $2\log\pi - \frac{\log 2}{2} - \log 3 \approx 0.844274$.

Proof. First, by induction we can compute the coefficients of $\widehat{A}_z(x)$ with respect to x using the Cauchy integral formula in the following form for integers $m \geqslant 0$:

$$\frac{1}{m!} \times \frac{\partial^{(m)}}{\partial z^{(m)}}\left[\frac{(\log x)^z}{1+P(2)z}\right] = \sum_{j=0}^{m} \frac{(-P(2))^{m-j}(\log\log x)^j}{j!} = e^{-\frac{\log\log x}{P(2)}} \frac{(-P(2))^m}{m!} \times \Gamma\left(m+1, -\frac{\log\log x}{P(2)}\right).$$

We have parameterized the contour around $|z| = r := \frac{k}{\log\log x}$. As $x \to \infty$ becomes unbounded and sufficiently large, and when $m \to \infty$ depending on x, we apply our standard asymptotic estimate of the incomplete gamma function to obtain that

$$\widehat{A}_{-z}(x) \sim \frac{(\log\log x)^{k-1}}{(k-1)!} \times \frac{x}{\log x} \cdot \frac{\zeta(2)^{k-1}}{\Gamma\left(1 - \frac{k}{\log\log x}\right)} \asymp \frac{x}{\log x} \cdot \frac{\zeta(2)^{k-1}(\log\log x)^{k-1}}{(k-1)!},$$

uniformly for $\log\log x - (\log\log x)^{2/3} \leqslant k \leqslant \log\log x$.

We now need something deeper about the distribution of $\Omega(n) - \omega(n)$ so that we can weight the signed terms with leading $\lambda(n)(-1)^{\omega(n)}$. The squarefree case is obvious, and in fact we can draw upon known results proved in [8, §2.4] that guarantee limiting asymptotic densities of the sets

$$d_k := \frac{1}{x} \cdot \#\{n \leqslant x : \Omega(n) - \omega(n) = k\} \sim \frac{3\hat{c}}{2} \cdot 2^{-k} + O(5^{-k}), \text{ as } x \to \infty.$$

The constant c is absolute and corresponds to the infinite prime product we defined earlier. We can assume, as is typical in justifying the canonical forms of the Erdös-Kac theorems for $\Omega(n)$ and $\omega(n)$, that for a random large $n \gg 1$, each of $(\omega(n), \Omega(n), \Omega(n) - \omega(n))$ are uniformly distributed as indicators of the prime factorization that arises for this n. With this assumption, for $1 \leqslant \omega(n) \leqslant \Omega(n) =: k$ we expect the sign of the terms $\lambda(n)(-1)^{\omega(n)}$ to obey the approximate density

$$\sum_{m=0}^{k} (-1)^m \cdot 2^{-m} = \hat{c} + \frac{(-1)^k \cdot \hat{c}}{4 \cdot 2^k}.$$

The leading unsigned term in the previous expansion is what yields the main term when we sum over powers of k.

Now we bound the magnitude of the following sums that we defined above by applying asymptotics for the incomplete gamma function in combination with Stirling's formula for x large:

$$\begin{aligned}\left|\sum_{k=1}^{\log\log x}\sum_{\substack{n\leqslant x\\ \Omega(n)=k}}\lambda(n)(-1)^{\omega(n)}C_k(n)\right| &\asymp \left|\sum_{k=1}^{\log\log x}\frac{\widehat{c}\cdot x\cdot\zeta(2)^{k-1}(\log\log x)^{k-1}}{(\log x)\cdot(k-1)!}\right| \\ &\asymp \frac{\widehat{c}}{\sqrt{2}\pi^{5/2}}\cdot\frac{x(\log x)^{2\log\pi-\frac{\log 2}{2}-\log 3}}{\sqrt{\log\log x}}.\end{aligned}$$

Notice that our uniform bounds on $\widehat{C}_k(x)$ proved above hold only when k depends on x and tends to infinity as $x\to\infty$. The summands we have used to obtain the bound in the previous formula capture the leading, most asymptotically significant term resulting from the Cauchy integral formula for $k\leqslant\log\log x-(\log\log x)^{2/3}$ in the initial range. We know from the reference that the significant contributions of the densities of the sets $\{n\leqslant x:\Omega(n)=k\}$ occur for k over the latter ranges so that the sum above is still accurate as $x\to\infty$. □

Proof of Theorem 8.3. For large x and $n\leqslant x$, define the following auxiliary variables:

$$\alpha_n := \frac{C_{\Omega(n)}(n)-\mu_n(C)}{\sigma_n(C)},\quad \beta_{n,x} := \frac{C_{\Omega(n)}(n)-\mu_x(C)}{\sigma_x(C)}.$$

Let the corresponding densities (whose limiting distributions we must verify) be defined by the functions

$$\Phi_1(x,z) := \frac{1}{x}\cdot\#\{n\leqslant x:\alpha_n\leqslant z\},$$

and

$$\Phi_2(x,z) := \frac{1}{x}\cdot\#\{n\leqslant x:\beta_{n,x}\leqslant z\}.$$

We first argue that it suffices to consider the distribution of $\Phi_2(x,z)$ as $x\to\infty$ in place of $\Phi_1(x,z)$ to obtain our desired result statement. In particular, the difference of the two auxiliary variables is neglibible as $x\to\infty$ for n,x taken over the ranges that contribute the non-trivial weight to the main term of each density function. We have for $\sqrt{x}\leqslant n\leqslant x$ and $C_{\Omega(n)}(n)\leqslant 2\cdot\mu_x(C)$ that

$$|\alpha_n-\beta_{n,x}| \ll \frac{1}{\sigma_x(C)}\xrightarrow{x\to\infty}0.$$

So we naturally prefer to estimate the easier forms of the distribution function $\Phi_2(x,z)$ when x is large, and for any fixed $z\in\mathbb{R}$. Much of the core of the next logic to our proof is adapted from the proof of Theorem 7.21 in the reference [8, §7.4]. In fact, we need to do little besides repeat the highlights of that argument to justify the form of the distribution of our limiting densities. The main adaptation from the proof in the reference is that we must replace $\log\log x\mapsto\frac{\pi^2}{6}\log\log x$.

For positive integers $k\geqslant 1$, write $k:=u+\zeta(2)\log\log x$, set the parameter $\delta_{u,x}:=\frac{u}{\zeta(2)\log\log x}$, and suppose initially that $|u|\leqslant\frac{\zeta(2)}{2}\log\log x$. As $x\to\infty$, we approximate

$$\frac{\zeta(2)^{k-1}(\log\log x)^{k-1}}{(k-1)!} = \frac{e^u(\log x)^{\zeta(2)}}{\sqrt{2\pi\zeta(2)\log\log x}}(1+\delta_{u,x})^{\frac{1}{2}-\zeta(2)\log\log x-u}\times\left(1+O\left(\frac{1}{\log\log x}\right)\right),$$

We have uniformly for $|\delta|\leqslant\frac{1}{2}$ that $\log(1+\delta)=\delta-\frac{\delta^2}{2}+O(|\delta|^3)$. So for the $\delta_{u,x}>0$ defined above satisfying this uniform bound, we obtain

$$(1+\delta_{u,x})^{\frac{1}{2}-\zeta(2)\log\log x-u} = \exp\left(-u+\frac{u-u^2}{2\zeta(2)\log\log x}-\frac{u^2}{4\zeta(2)^2(\log\log x)^2}+O\left(\frac{|u|^3}{(\log\log x)^3}\right)\right).$$

We complete the estimates as in the reference to verify consistent asymptotics for the cases where $\log\log x - (\log\log x)^{2/3} \leqslant k \leqslant (\log\log x)^{2/3}$, $|u| \leqslant 1$, and $|u| > 1$. This leads to

$$\frac{\zeta(2)^{k-1}(\log\log x)^{k-1}}{(k-1)!} = \frac{(\log x)^{\zeta(2)}}{\sqrt{2\pi\zeta(2)\log\log x}} \exp\left(-\frac{u^2}{2\zeta(2)\log\log x}\right)(1+o(1))\,, \text{ as } x \rightarrow \infty.$$

Thus, we see that

$$\frac{\widehat{C}_k(x)}{x} = \frac{\widehat{c}}{(\log x)^{1-\zeta(2)}\sqrt{2\pi \cdot \zeta(2)\log\log x}} \exp\left(-\frac{(k-\zeta(2)\log\log x)^2}{2\zeta(2)\log\log x}\right)(1+o(1)), \text{ as } x \rightarrow \infty.$$

Then we conclude the result by summing over the asymptotically weighted range where $\left(\zeta(2)^{-1}\log\log x\right) - (\log\log x)^{2/3} \leqslant k \leqslant \zeta(2)^{-1}\log\log x + z\left(\zeta(2)^{-1}\log\log x\right)^{1/2}$. □

Remark 8.7. Note that technically, the multiplier and scaling by the reciprocal power of $\log x$ prevent us from getting a *probability* distribution proper from these estimates in Corollary 8.3. This indicates that our choices for the mean and variance analogs in a central limit theorem from a probabilistic setting, while convenient and natural following from the model proof in the reference, are slightly imprecise in describing the distribution of this particular arithmetic function case, Nonetheless, as $x \rightarrow \infty$, the result we do prove provides useful intuition about the values of key arithmetic functions that are components in building the values and distribution of $g^{-1}(n)$ via divisor sums over $n \leqslant x$.

Proof of Corollary 8.4. We compute using the argument sketched in the proof of Corollary 6.6 from Section 6.3 that

$$|g^{-1}(n)| - \mathbb{E}|g^{-1}(n)| \sim \frac{6}{\pi^2} C_{\Omega(n)}(n).$$

Then the result follows from Theorem 8.3. In particular, we shift, scale, and then take the absolute value of the arithmetic functions $\lambda(n)(-1)^{\omega(n)}C_{\Omega(n)}(n)$ that resulted in the known limiting densities in the first theorem. In particular, what we arrive at is the task of estimating

$$\frac{1}{x}\#\left\{n \leqslant x : -\frac{\pi^2}{6}|z+\mu_x(C)| \leqslant \frac{\lambda(n)(-1)^{\omega(n)}C_{\Omega(n)}(n)}{\sigma_x(C)} \leqslant \frac{\pi^2}{6}|z+\mu_x(C)|\right\},$$

as $x \rightarrow \infty$ for $w_x(z) := \frac{\pi^2}{6}|z+\mu_x(C)|$ defined as in the statement of the result. □

Table T.1: ***Computations with*** $\mathbf{g^{-1}(n) \equiv (\omega+1)^{-1}(n)}$ ***for*** $\mathbf{1 \leqslant n \leqslant 500}$**.**

- ► *The column labeled* `Primes` *provides the prime factorization of each n so that the values of $\omega(n)$ and $\Omega(n)$ are easily extracted. The columns labeled* `Sqfree` *and* `PPower`*, respectively, list inclusion of n in the sets of squarefree integers and the prime powers.*
- ► *The next three columns provide the explicit values of the inverse function $g^{-1}(n)$ and compare its explicit value with other estimates. We define the function $\widehat{f}_1(n) := \sum_{k=0}^{\omega(n)} \binom{\omega(n)}{k} \cdot k!$.*
- ► *The last several columns indicate properties of the summatory function of $g^{-1}(n)$. The notation for the densities of the sign weight of $g^{-1}(n)$ is defined as $\mathcal{L}_{\pm}(x) := \frac{1}{n} \cdot \#\{n \leqslant x : \lambda(n) = \pm 1\}$. The last three columns then show the explicit components to the signed summatory function, $G^{-1}(x) := \sum_{n \leqslant x} g^{-1}(n)$, decomposed into its respective positive and negative magnitude sum contributions: $G^{-1}(x) = G_+^{-1}(x) + G_-^{-1}(x)$ where $G_+^{-1}(x) > 0$ and $G_-^{-1}(x) < 0$ for all $x \geqslant 1$.*
