Abstract

The Dirichlet inverse function $g(n) := (\omega + 1)^{-1}(n)$ is defined in terms of the shifted strongly additive function $\omega(n)$ that counts the number of distinct prime factors of n without multiplicity. We prove exact formulas expressing g(n) in terms of the auxiliary unsigned function $C_{\Omega}(n)$ whose DGF is given by $(1 - P(s))^{-1}$ for Re(s) > 1 where $P(s) := \sum_{p} p^{-s}$ is the prime zeta function. The unsigned functions $C_{\Omega}(n)$ and |g(n)| belong to the class of arithmetic functions we term as factorization symmetric. Any arithmetic function that is factorization symmetric has distinct values that are repeated along identical partitions of the exponents of the distinct prime divisors of any $n \ge 2$. The summatory functions of factorization symmetric functions are amenable to an application of the Selberg-Delange method. A special case of the method is applied in the article to formulate asymptotics for the restricted partial sums of $C_{\Omega}(n)$ over all $n \le x$ such that $\Omega(n) = k$ which hold uniformly for all $1 \le k \le \frac{3}{2} \log \log x$.

We conjecture that there is a limiting probability measure on \mathbb{R} with cumulative density function Φ_{Ω} and an absolute constant $B_0 > 0$ such that the following holds for any real y as $x \to \infty$:

$$\frac{1}{x} \times \left\{ 3 \le n \le x : \frac{|g(n)| - \frac{6}{\pi^2 n} \times \sum_{k \le n} |g(k)| - B_0 \sqrt{\log \log \log x}}{B_0 \sqrt{(\log x)(\log \log \log x)}} \le y \right\} = \Phi_{\Omega} \left(\frac{\pi^2 y}{6} \right) + o(1).$$

The Mertens function, $M(x) := \sum_{n \le x} \mu(n)$, is defined as the summatory function of the classical Möbius function for $x \ge 1$. Discrete convolutions of the partial sums

$$G(x) \coloneqq \sum_{n \le x} \lambda(n) |g(n)|,$$

with the prime counting function $\pi(x)$ determine new exact formulas for M(x). In this way, we prove another concrete link between the Mertens function and the distribution of the partial sums $L(x) := \sum_{n \le x} \lambda(n)$ and connect these two summatory functions with explicit probability distributions at large x.

Keywords and Phrases: Möbius function; Mertens function; Dirichlet inverse; Liouville lambda function; prime omega function; prime counting function; Dirichlet generating function; prime zeta function; Erdős-Kac theorem.

1 Introduction

The Mertens function is the summatory function of $\mu(n)$ defined by the partial sums [27, A008683; A002321]

$$M(x) = \sum_{n \le x} \mu(n)$$
, for $x \ge 1$.

The Mertens function is related to the partial sums of the Liouville lambda function, denoted by $L(x) := \sum_{n \le x} \lambda(n)$, via the relation [11, 17] [27, A008836; A002819]

$$L(x) = \sum_{d \le \sqrt{x}} M\left(\left\lfloor \frac{x}{d^2} \right\rfloor\right), \text{ for } x \ge 1.$$

The focus of the article is on studying statistics of the unsigned functions $C_{\Omega}(n)$ and |g(n)| and their partial sums (defined below). The Mertens function has exact expressions by discrete convolutions of the classical prime counting function $\pi(x)$ and the signed partial sums of g(n). These new formulas for M(x) provide a window from which we can view classically difficult problems about asymptotics for this function partially in terms of the properties of the auxiliary unsigned functions and their distributions. Preliminary numerical computations of these functions and their partial sums suggests the intuition that these primitives will be easier objects to work with and hence bound in limiting cases as the subject of future work to extend the results in this article.

We fix the notation for the Dirichlet inverse function defined by [27, A341444]

$$g(n) := (\omega + 1)^{-1}(n), \text{ for } n \ge 1.$$
 (1.1)

We use the notation |g(n)| to denote the absoute value of g(n). An exact expression for g(n) is given by (see Lemma 4.3 and Corollary 4.4)

$$g(n) = \lambda(n) \times \sum_{d|n} \mu^2 \left(\frac{n}{d}\right) C_{\Omega}(d), n \ge 1, \tag{1.2}$$

where the sequence $\lambda(n)C_{\Omega}(n)$ has the DGF $(1+P(s))^{-1}$ and $C_{\Omega}(n)$ has the DGF $(1-P(s))^{-1}$ for Re(s) > 1 (see Proposition 4.2). The function $C_{\Omega}(n)$ was considered in [9] with an exact formula given by [13, cf. §3]

$$C_{\Omega}(n) = \begin{cases} 1, & \text{if } n = 1; \\ (\Omega(n))! \times \prod_{p^{\alpha} \mid |n} \frac{1}{\alpha!}, & \text{if } n \ge 2. \end{cases}$$
 (1.3)

The function $C_{\Omega}(n)$ that is identified as a key auxiliary sequence in the explicit formula from (1.2) is considered under alternate notation by Fröberg (circa 1968) in his work on the series expansions of the prime zeta function, $P(s) := \sum_{p} p^{-s}$ for Re(s) > 1. The connection of the function $C_{\Omega}(n)$ to M(x) is unique to our work to establish properties of this sequence.

Definition 1.1. For $n \geq 2$, let the function $\mathcal{E}[n] \vdash (\alpha_1, \alpha_2, \dots, \alpha_r)$ denote the unordered partition of exponents for which $n = p_1^{\alpha_1} \times \dots \times p_r^{\alpha_r}$ is the factorization of n into powers of distinct primes. An arithmetic function $f: \mathbb{Z}^+ \to \mathbb{C}$ has property \mathcal{P}_{FS} if the following holds for all $n_1, n_2 \geq 2$:

$$\mathcal{E}[n_1] = \mathcal{E}[n_2] \implies f(n_1) = f(n_2).$$

We say that any arithmetic function that has property \mathcal{P}_{FS} is factorization symmetric.

The unsigned auxiliary functions $C_{\Omega}(n)$ and |g(n)| are both factorization symmetric. The canonical strongly additive number theoretic functions given by the prime omega functions, $\omega(n)$ and $\Omega(n)$, are factorization symmetric. The class of factorization symmetric arithmetic functions is closed under Dirichlet convolution. If $f_{\omega} \geq 0$ is a factorization symmetric function with $f_{\omega}(1) = 0$, then the Dirichlet inverse $(f_{\omega} + 1)^{-1}(n)$ is factorization symmetric and $\operatorname{sgn}((f_{\omega} + 1)^{-1}(n)) = \lambda(n)$. The class of factorization symmetric functions yields an approach by the Selberg-Delange method in [29, §II.6.1] to express asymptotics for its partial sums.

We define the function

$$\widehat{G}(z) := \frac{\zeta(2)^{-z}}{\Gamma(1+z)(1+P(2)z)}, \text{ for } 0 \le |z| < P(2)^{-1} \approx 2.21118.$$

We then use the results proved in the application of the Selberg-Delange method in Theorem 2.2 and its consequence in Theorem 3.3 to obtain the next corollary for an absolute constant $A_0 > 0$.

Corollary 1.2. We have uniformly for $1 \le k \le \frac{3}{2} \log \log x$ that at all sufficiently large x

$$\sum_{\substack{n \le x \\ \Omega(n) = k}} C_{\Omega}(n) = \frac{A_0 \sqrt{2\pi}x}{\log x} \times \widehat{G}\left(\frac{k-1}{\log\log x}\right) \frac{(\log\log x)^{k-\frac{1}{2}}}{(k-1)!} \left(1 + O\left(\frac{1}{\log\log x}\right)\right).$$

We use Corollary 1.2 with an adaptation of the form of Rankin's method from [18, Thm. 7.20] to prove the following theorem which gives the average order of $C_{\Omega}(n)$:

Theorem 1.3. There is an absolute constant $B_0 > 0$ such that as $n \to \infty$

$$\frac{1}{n} \times \sum_{k \le n} C_{\Omega}(k) = B_0 \sqrt{\log \log n} \left(1 + O\left(\frac{1}{\log \log n}\right) \right).$$

Corollary 1.4. We have that as $n \to \infty$

$$\frac{1}{n} \times \sum_{k \le n} |g(k)| = \frac{6B_0(\log n)\sqrt{\log \log n}}{\pi^2} \left(1 + O\left(\frac{1}{\log \log n}\right)\right).$$

Proposition 1.5. We have the following properties of the Dirichlet inverse function g(n):

- (A) For all $n \ge 1$, $\operatorname{sgn}(g(n)) = \lambda(n)$;
- (B) For all squarefree integers $n \ge 1$, we have that

$$|g(n)| = \sum_{m=0}^{\omega(n)} {\omega(n) \choose m} \times m!.$$

The realization of the beautiful combinatorial form of property (B) in Proposition 1.5 motivates our pursuit of simpler expressions for g(n) at any $n \ge 1$. The next conjecture provides a more complete picture of the distribution of the unsigned inverse sequence whose values are exactly identified by the formulas in Proposition 1.5 along squarefree $n \ge 1$ (see Conjecture 5.1 and Corollary 5.2).

Conjecture. There is a limiting probability measure ϕ_{Ω} on \mathbb{R} with corresponding CDF given by Φ_{Ω} so that for any $y \in (-\infty, +\infty)$ we have that as $x \to \infty$

$$\frac{1}{x} \times \# \left\{ 3 \le n \le x : \frac{|g(n)| - \frac{6}{\pi^2 n} \times \sum_{k \le n} |g(k)| - B_0 \sqrt{\log \log \log x}}{B_0 \sqrt{(\log x)(\log \log \log x)}} \le y \right\} = \Phi_{\Omega} \left(\frac{\pi^2 y}{6} \right) + o(1). \tag{1.4}$$

We define the partial sums G(x) for integers $x \ge 1$ as follows [27, A341472]:

$$G(x) := \sum_{n \le x} g(n) = \sum_{n \le x} \lambda(n) |g(n)|.$$
 (1.5)

Theorem 1.6. For all $x \ge 1$, we have that

$$M(x) = \sum_{1 \le k \le x} g(k) \left(\pi \left(\left\lfloor \frac{x}{k} \right\rfloor \right) + 1 \right), \tag{1.6a}$$

$$M(x) = G(x) + \sum_{k=1}^{\frac{x}{2}} G(k) \left(\pi \left(\left\lfloor \frac{x}{k} \right\rfloor \right) - \pi \left(\left\lfloor \frac{x}{k+1} \right\rfloor \right) \right), \tag{1.6b}$$

$$M(x) = G(x) + \sum_{p \le x} G\left(\left\lfloor \frac{x}{p} \right\rfloor\right). \tag{1.6c}$$

We expect substantial local cancellation in the terms involving G(x) in our new formulas for M(x) at almost every large x (cf. Section 6.2). Since we prove that $\operatorname{sgn}(g(n)) = \lambda(n)$ for all $n \ge 1$ in Proposition 4.2, the partial sums defined by G(x) are precisely related to the properties of |g(n)| and asymptotics for L(x). Stating tight bounds on the properties of the distribution of L(x) is still viewed as a problem that is equally as difficult as understanding the properties of M(x) well at large x or along infinite subsequences.

2 An application of the Selberg-Delange method

Definition 2.1. Let the bivariate DGF $\widehat{F}(s,z)$ be defined for Re(s) > 1 and $|z| < |P(s)|^{-1}$ by

$$\widehat{F}(s,z) \coloneqq \frac{1}{1 + P(s)z} \times \prod_{p} \left(1 - \frac{1}{p^s}\right)^z.$$

Let the partial sums, $\widehat{A}_z(x)$, be defined for any $x \ge 1$ by

$$\widehat{A}_z(x) \coloneqq \sum_{n \le x} (-1)^{\omega(n)} C_{\Omega}(n) z^{\Omega(n)}.$$

The function $C_{\Omega}(n)$ defined in equation (1.3) of the introduction is discussed in depth within Section 3.

The formula for the partial sums of the coefficients of the DGF expansion of $\widehat{F}(s,z)$ we prove in Theorem 2.2 are derived by applying asymptotics for the partial sums of the coefficients of the DGF $\zeta(s)^z$, denoted by $D_z(x)$ for $x \ge 1$ and 0 < |z| < 2. The latter asymptotics are proved in [18, §7.4] using a Hankel contour method. The strategy behind the proof of the next theorem is formed as an extension of the Selberg-Delange convolution method from [29, §II.6.1]. Our choice of the z-dependent function $\widehat{F}(s,z)\zeta(s)^z$ given in the next definition is motivated by the exact formula for $C_{\Omega}(n)$ expanded in (1.3). We then apply the extension of Tenenbaum's Selberg-Delange method proofs to extract an asymptotic formula for the coefficients of $\widehat{F}(s,z)\zeta(s)^z$ in the theorem below.

Theorem 2.2. We have for all sufficiently large $x \ge 2$ and any $|z| < P(2)^{-1} \approx 2.21118$ that

$$\widehat{A}_z(x) = \frac{x\widehat{F}(2,z)}{\Gamma(z)} (\log x)^{z-1} + O_z \left(x(\log x)^{\operatorname{Re}(z)-2} \right).$$

Proof. It follows from (1.3) that we can generate exponentially scaled forms of the function $C_{\Omega}(n)$ by a product identity of the following form:

$$\sum_{n \geq 1} \frac{C_{\Omega}(n)}{(\Omega(n))!} \cdot \frac{(-1)^{\omega(n)} z^{\Omega(n)}}{n^s} = \prod_{p} \left(1 + \sum_{r \geq 1} \frac{z^{\Omega(p^r)}}{r! p^{rs}} \right)^{-1} = \exp\left(-z P(s) \right), \text{ for } \operatorname{Re}(s) > 1 \text{ and } \operatorname{Re}(P(s)z) > -1.$$

This Euler type product expansion is similar in construction to the parameterized bivariate DGFs defined in [18, §7.4] [29, cf. §II.6.1]. By computing a termwise Laplace transform applied to the right-hand-side of the previous equation, we obtain that

$$\sum_{n\geq 1} \frac{C_{\Omega}(n)(-1)^{\omega(n)}z^{\Omega(n)}}{n^s} = \int_0^\infty e^{-t} \exp\left(-tzP(s)\right) dt = \frac{1}{1+P(s)z}, \text{ for } \operatorname{Re}(s) > 1 \text{ and } \operatorname{Re}(P(s)z) > -1.$$

It follows from the Euler product representation of $\zeta(s)$, which is convergent for any Re(s) > 1, that

$$\widehat{F}(s,z)\zeta(s)^z = \sum_{n>1} \frac{(-1)^{\omega(n)} C_{\Omega}(n) z^{\Omega(n)}}{n^s}, \text{ for } \text{Re}(s) > 1 \text{ and } |z| < |P(s)|^{-1}.$$

The DGF $\widehat{F}(s,z)$ is an analytic function of s for all Re(s) > 1 whenever the parameter $|z| < |P(s)|^{-1}$. Indeed, if the sequence $\{b_z(n)\}_{n\geq 1}$ indexes the coefficients in the DGF expansion of $\widehat{F}(s,z)\zeta(s)^z$, then the series

$$\left| \sum_{n>1} \frac{b_z(n)(\log n)^{2R+1}}{n^s} \right| < +\infty.$$

Moreover, the series in the last equation is uniformly bounded for all $\text{Re}(s) \ge 2$ and $|z| \le R < |P(s)|^{-1}$. For fixed 0 < |z| < 2, let the sequence $\{d_z(n)\}_{n\ge 1}$ be generated as the coefficients of the DGF

$$\zeta(s)^z = \sum_{n>1} \frac{d_z(n)}{n^s}$$
, for Re(s) > 1.

The corresponding summatory function of $d_z(n)$ is defined by $D_z(x) := \sum_{n \le x} d_z(n)$. The theorem proved by contour integration in [18, Thm. 7.17; §7.4] shows that for any 0 < |z| < 2 and all integers $x \ge 2$ we have

$$D_z(x) = \frac{x(\log x)^{z-1}}{\Gamma(z)} + O_z\left(x(\log x)^{\operatorname{Re}(z)-2}\right).$$

Let $b_z(n) \coloneqq (-1)^{\omega(n)} C_{\Omega}(n) z^{\Omega(n)}$, set the convolution $\hat{a}_z(n) \coloneqq \sum_{d \mid n} b_z(d) d_z\left(\frac{n}{d}\right)$, and take its partial sums to be $\widehat{A}_z(x) \coloneqq \sum_{n \le x} \hat{a}_z(n)$. Then we have that

$$\widehat{A}_{z}(x) = \sum_{m \leq \frac{x}{2}} b_{z}(m) D_{z}\left(\frac{x}{m}\right) + \sum_{\frac{x}{2} < m \leq x} b_{z}(m)$$

$$= \frac{x}{\Gamma(z)} \times \sum_{m \leq \frac{x}{2}} \frac{b_{z}(m)}{m} \log\left(\frac{x}{m}\right)^{z-1} + O\left(\sum_{m \leq x} \frac{x|b_{z}(m)|}{m} \times \log\left(\frac{2x}{m}\right)^{\operatorname{Re}(z)-2}\right). \tag{2.1}$$

We can sum the coefficients $\frac{b_z(m)}{m}$ for integers $m \le u$ when u is taken sufficiently large as follows:

$$\sum_{m \le u} \frac{b_z(m)}{m^2} \times m = (\widehat{F}(2, z) + O_z(u^{-2})) u - \int_1^u (\widehat{F}(2, z) + O_z(t^{-2})) dt = \widehat{F}(2, z) + O_z(u^{-1}).$$

Suppose that $0 < |z| \le R < P(2)^{-1}$. For large x, the error term in (2.1) satisfies

$$\sum_{m \le x} \frac{x|b_z(m)|}{m} \log \left(\frac{2x}{m}\right)^{\text{Re}(z)-2} \ll x(\log x)^{\text{Re}(z)-2} \times \sum_{m \le \sqrt{x}} \frac{|b_z(m)|}{m} + x(\log x)^{-(R+2)} \times \sum_{m > \sqrt{x}} \frac{|b_z(m)|}{m} (\log m)^{2R},$$

$$= O_z \left(x (\log x)^{\operatorname{Re}(z) - 2} \right),$$

whenever $0 < |z| \le R$. When $m \le \sqrt{x}$ we have that

$$\log\left(\frac{x}{m}\right)^{z-1} = (\log x)^{z-1} + O\left((\log m)(\log x)^{\operatorname{Re}(z)-2}\right).$$

A related upper bound is obtained for the left-hand-side of the previous equation when $\sqrt{x} < m < x$ and 0 < |z| < R. The combined sum over the interval $m \le \frac{x}{2}$ corresponds to bounding the sum components when $0 < |z| \le R$ by

$$\sum_{m \le \frac{x}{2}} b_{z}(m) D_{z} \left(\frac{x}{m}\right) = \frac{x}{\Gamma(z)} (\log x)^{z-1} \times \sum_{m \le \frac{x}{2}} \frac{b_{z}(m)}{m} + O_{R} \left(x (\log x)^{\operatorname{Re}(z)-2} \times \sum_{m \le \sqrt{x}} \frac{|b_{z}(m)| \log m}{m} + x (\log x)^{R-1} \times \sum_{m > \sqrt{x}} \frac{|b_{z}(m)|}{m}\right) \\
= \frac{x \widehat{F}(2, z)}{\Gamma(z)} (\log x)^{z-1} + O_{R} \left(x (\log x)^{\operatorname{Re}(z)-2} \times \sum_{m \ge 1} \frac{b_{z}(m) (\log m)^{2R+1}}{m^{2}}\right) \\
= \frac{x \widehat{F}(2, z)}{\Gamma(z)} (\log x)^{z-1} + O_{R} \left(x (\log x)^{\operatorname{Re}(z)-2}\right). \qquad \Box$$

3 Properties of the function $C_{\Omega}(n)$

Definition 3.1. We define the following bivariate sequence for integers $n \ge 1$ and $k \ge 0$:

$$C_k(n) := \begin{cases} \varepsilon(n), & \text{if } k = 0; \\ \sum_{d|n} \omega(d) C_{k-1} \left(\frac{n}{d}\right), & \text{if } k \ge 1. \end{cases}$$

$$(3.1)$$

Using the more standardized definitions in [2, §2], we can alternately identify the k-fold convolution of ω with itself in the following notation: $C_0(n) \equiv \omega^{0*}(n)$ and $C_k(n) \equiv \omega^{k*}(n)$ for integers $k \geq 1$ and $n \geq 1$. The special case of (3.1) where $k \coloneqq \Omega(n)$ occurs frequently in the next sections of the article. To avoid cumbersome notation when referring to this common function variant, we suppress the duplicate index n by writing $C_{\Omega}(n) \coloneqq C_{\Omega(n)}(n)$.

By recursively expanding the definition of $C_k(n)$ at any fixed $n \ge 2$, we see that we can form a chain of at most $\Omega(n)$ iterated (or nested) divisor sums by unfolding the definition of (3.1) inductively. By the same argument, we see that at fixed n, the function $C_k(n)$ is non-zero only possibly when $1 \le k \le \Omega(n)$ whenever $n \ge 2$. A sequence of signed semi-diagonals of the functions $C_k(n)$ begins as follows [27, A008480]:

$$\{\lambda(n)C_{\Omega}(n)\}_{n\geq 1} = \{1, -1, -1, 1, -1, 2, -1, -1, 1, 2, -1, -3, -1, 2, 2, 1, -1, -3, -1, -3, 2, 2, -1, 4, 1, 2, \ldots\}.$$

We see by (1.3) that $C_{\Omega}(n) \leq (\Omega(n))!$ for all $n \geq 1$ with equality precisely at the squarefree integers so that $(\Omega(n))! = (\omega(n))!$ whenever $\mu^2(n) = 1$.

3.1 Uniform asymptotics for partial sums

The arguments given in the next proofs are new while mimicking as closely as possible the spirit of the proofs we cite inline from the references [18, 29].

Definition 3.2. For integers $x \ge 3$ and $k \ge 1$, let

$$\widehat{C}_{k,*}(x) \coloneqq \sum_{\substack{n \le x \\ \Omega(n) = k}} (-1)^{\omega(n)} C_{\Omega}(n).$$

Let the corresponding unsigned sums for integers $x \ge 3$ and $k \ge 1$ by

$$\widehat{C}_k(x) \coloneqq \sum_{\substack{n \le x \\ \Omega(n) = k}} C_{\Omega}(n).$$

Let $\widehat{G}(z) \coloneqq \widehat{F}(2,z) \times \Gamma(1+z)^{-1}$ when $0 \le |z| < P(2)^{-1}$, where $\widehat{F}(2,z)$ is defined as in Theorem 2.2.

Theorem 3.3. As $x \to \infty$, we have uniformly for any $1 \le k \le 2 \log \log x$ that

$$\widehat{C}_{k,*}(x) = -\widehat{G}\left(\frac{k-1}{\log\log x}\right) \frac{x}{\log x} \cdot \frac{(\log\log x)^{k-1}}{(k-1)!} \left(1 + O\left(\frac{k}{(\log\log x)^2}\right)\right).$$

Proof. When k = 1, we have that $\Omega(n) = \omega(n)$ for all $n \le x$ such that $\Omega(n) = k$. The positive integers n that satisfy this requirement are precisely the primes $p \le x$. Hence, the formula is satisfied as

$$\sum_{p \le x} (-1)^{\omega(p)} C_{\Omega}(p) = -\sum_{p \le x} 1 = -\frac{x}{\log x} \left(1 + O\left(\frac{1}{\log x}\right) \right).$$

Since $O((\log x)^{-1}) = O((\log \log x)^{-2})$ as $x \to \infty$, we obtain the required error term for the bound at k = 1. For $2 \le k \le 2 \log \log x$, we will apply the error estimate from Theorem 2.2 with $r := \frac{k-1}{\log \log x}$ in the formula

$$\widehat{C}_{k,*}(x) = \frac{(-1)^{k+1}}{2\pi i} \times \int_{|v|=r} \frac{\widehat{A}_{-v}(x)}{v^{k+1}} dv.$$

The error in this formula contributes terms that are bounded by

$$\left| x(\log x)^{-(\operatorname{Re}(v)+2)} v^{-(k+1)} \right| \ll \left| x(\log x)^{-(r+2)} r^{-(k+1)} \right| \ll \frac{x}{(\log x)^{2-\frac{k-1}{\log\log x}}} \cdot \frac{(\log\log x)^k}{(k-1)^k} \\
\ll \frac{x}{(\log x)^2} \cdot \frac{(\log\log x)^{k+1}}{(k-1)^{\frac{1}{2}}(k-1)!} \ll \frac{x}{\log x} \cdot \frac{k(\log\log x)^{k-5}}{(k-1)!}, \text{ as } x \to \infty.$$

We next find the main term for the coefficients of the following contour integral when $r \in [0, z_{\text{max}}] \subseteq [0, P(2)^{-1})$:

$$\widehat{C}_{k,*}(x) \sim \frac{(-1)^{k+1}x}{2\pi \imath (\log x)} \times \int_{|v|=r} \frac{(\log x)^{-v} \zeta(2)^v}{\Gamma(1-v)v^k (1-P(2)v)} dv. \tag{3.2}$$

The main term of $\widehat{C}_{k,*}(x)$ is then given by $-\frac{x}{\log x} \times I_k(r,x)$, where we define

$$I_{k}(r,x) = \frac{1}{2\pi i} \times \int_{|v|=r} \frac{\widehat{G}(v)(\log x)^{v}}{v^{k}} dv$$

=: $I_{1,k}(r,x) + I_{2,k}(r,x)$.

Taking $r = \frac{k-1}{\log \log x}$, the first of the component integrals is defined to be

$$I_{1,k}(r,x) := \frac{\widehat{G}(r)}{2\pi i} \times \int_{|v|=r} \frac{(\log x)^v}{v^k} dv = \widehat{G}(r) \times \frac{(\log \log x)^{k-1}}{(k-1)!}.$$

The second integral, $I_{2,k}(r,x)$, corresponds to another error term in our approximation. This component function is defined by

$$I_{2,k}(r,x) \coloneqq \frac{1}{2\pi i} \times \int_{|v|=r} \left(\widehat{G}(v) - \widehat{G}(r)\right) \frac{(\log x)^v}{v^k} dv.$$

Integrating by parts shows that [18, cf. Thm. 7.19; §7.4]

$$\frac{(r-v)}{2\pi i} \times \int_{|v|=r} (\log x)^v v^{-k} dv = 0,$$

so that integrating by parts once again we have

$$I_{2,k}(r,x) := \frac{1}{2\pi i} \times \int_{|v|=r} \left(\widehat{G}(v) - \widehat{G}(r) - \widehat{G}'(r)(v-r) \right) (\log x)^v v^{-k} dv.$$

We find that

$$\left|\widehat{G}(v)-\widehat{G}(r)-\widehat{G}'(r)(v-r)\right| = \left|\int_{r}^{v} (v-w)\widehat{G}''(w)dw\right| \ll |v-r|^{2}.$$

With the parameterization $v = re^{2\pi i\theta}$ for $\theta \in \left[-\frac{1}{2}, \frac{1}{2}\right]$ (again selecting $r \coloneqq \frac{k-1}{\log\log x}$), we obtain

$$|I_{2,k}(r,x)| \ll r^{3-k} \times \int_{-\frac{1}{2}}^{\frac{1}{2}} (\sin \pi \theta)^2 e^{(k-1)\cos(2\pi\theta)} d\theta.$$

Since $|\sin x| \le |x|$ for all |x| < 1 and $\cos(2\pi\theta) \le 1 - 8\theta^2$ if $-\frac{1}{2} \le \theta \le \frac{1}{2}$, we arrive at the next bounds at any $1 \le k \le 2\log\log x$ when $r = \frac{k-1}{\log\log x}$.

$$|I_{2,k}(r,x)| \ll r^{3-k} e^{k-1} \times \int_0^\infty \theta^2 e^{-8(k-1)\theta^2} d\theta$$

$$\ll \frac{r^{3-k} e^{k-1}}{(k-1)^{\frac{3}{2}}} = \frac{(\log \log x)^{k-3} e^{k-1}}{(k-1)^{k-\frac{3}{2}}} \ll \frac{k(\log \log x)^{k-3}}{(k-1)!}.$$

Finally, whenever $1 \le k \le 2 \log \log x$ we have

$$1 = \widehat{G}(0) \ge \widehat{G}\left(\frac{k-1}{\log\log x}\right) = \frac{1}{\Gamma\left(1 + \frac{k-1}{\log\log x}\right)} \times \frac{\zeta(2)^{\frac{1-k}{\log\log x}}}{\left(1 + \frac{P(2)(k-1)}{\log\log x}\right)} \ge \widehat{G}(2) \approx 0.097027.$$

In particular, the function $\widehat{G}\left(\frac{k-1}{\log \log x}\right) \gg 1$ for all $1 \le k \le 2 \log \log x$.

Proof of Corollary 1.2. Suppose that $\hat{h}(t)$ and $\sum_{n \leq t} \lambda_*(n)$ are piecewise smooth and differentiable functions of t on \mathbb{R}^+ . The next integral formulas result by Abel summation and integration by parts.

$$\sum_{n \le x} \lambda_*(n) \hat{h}(n) = \left(\sum_{n \le x} \lambda_*(n)\right) \hat{h}(x) - \int_1^x \left(\sum_{n \le t} \lambda_*(n)\right) \hat{h}'(t) dt$$
 (3.3a)

$$\sim \int_{1}^{x} \frac{d}{dt} \left[\sum_{n \le t} \lambda_{*}(n) \right] \hat{h}(t) dt \tag{3.3b}$$

We transform our previous results for the partial sums of $(-1)^{\omega(n)}C_{\Omega}(n)$ such that $\Omega(n)=k$ from Theorem 3.3 to approximate the corresponding partial sums of only the unsigned function $C_{\Omega}(n)$ over these $n \leq x$. Since $1 \leq k \leq \frac{3}{2} \log \log x$, we have that

$$\widehat{C}_{k,*}(x) = \sum_{\substack{n \leq x \\ \Omega(n) = k}} (-1)^{\omega(n)} C_{\Omega}(n) = \sum_{n \leq x} (-1)^{\omega(n)} \left[\omega(n) \leq \frac{3}{2} \log \log x \right]_{\delta} \times C_{\Omega}(n) \left[\Omega(n) = k \right]_{\delta}.$$

By the proof of Lemma D.5, we have that as $t \to \infty$

$$L_*(t) := \sum_{\substack{n \le t \\ \omega(n) \le \frac{3}{2} \log \log t}} (-1)^{\omega(n)} = \frac{(-1)^{\lfloor \log \log t \rfloor} t}{A_0 \sqrt{2\pi \log \log t}} \left(1 + O\left(\frac{1}{\sqrt{\log \log t}}\right) \right). \tag{3.4}$$

Except for t within a subset of $(0, \infty)$ of measure zero on which $L_*(t)$ may change sign, the main term of the derivative of this summatory function is approximated almost everywhere by

$$L'_*(t) \sim \frac{(-1)^{\lfloor \log \log t \rfloor}}{A_0 \sqrt{2\pi \log \log t}}$$
, a.e. for $t > e$.

We apply the formula from (3.3b), to deduce that as $x \to \infty$ whenever $1 \le k \le \frac{3}{2} \log \log x$

$$\widehat{C}_{k,*}(x) \sim \sum_{j=1}^{\log\log x - 1} \frac{2(-1)^{j+1}}{A_0\sqrt{2\pi}} \times \int_{e^{e^j}}^{e^{e^{j+1}}} \frac{C_{\Omega}(t) \left[\Omega(t) = k\right]_{\delta}}{\sqrt{\log\log t}} dt$$

$$\sim -\int_{1}^{\frac{\log\log x}{2}} \int_{e^{e^{2s-1}}}^{e^{e^{2s}}} \frac{2C_{\Omega}(t) \left[\Omega(t) = k\right]_{\delta}}{A_0\sqrt{2\pi} \log\log t} dt ds + \frac{1}{A_0\sqrt{2\pi}} \times \int_{e^e}^{x} \frac{C_{\Omega}(t) \left[\Omega(t) = k\right]_{\delta}}{\sqrt{\log\log t}} dt.$$

For large x, $(\log \log t)^{-\frac{1}{2}}$ is continuous and monotone decreasing for t on $\left[x^{e^{-1}}, x\right]$ with

$$\frac{1}{\sqrt{\log\log x}} - \frac{1}{\sqrt{\log\log\left(x^{e^{-1}}\right)}} = O\left(\frac{1}{(\log x)\sqrt{\log\log x}}\right),\,$$

Hence, we have that

$$-A_0\sqrt{2\pi}x(\log x)\sqrt{\log\log x}\times\widehat{C}'_{k,*}(x) = \left(\widehat{C}_k(x)-\widehat{C}_k\left(x^{e^{-1}}\right)\right)(1+o(1))-x(\log x)\widehat{C}'_k(x). \tag{3.5}$$

For $1 \le k < \frac{3}{2} \log \log x$, we expect contributions from the squarefree integers $n \le x$ such that $\omega(n) = \Omega(n) = k$ to be on the order of

$$\widehat{C}_k(x) \gg \widehat{\pi}_k(x) \times \frac{x}{\log x} \times \frac{(\log \log x)^{k-1}}{(k-1)!}.$$

The argument used to justify the last equation is that for any integers $k \geq 2$ we find

$$|\widehat{C}_k(x)| \gg \sum_{n \le x} [\Omega(n) = k]_{\delta}.$$

We conclude that $\widehat{C}_k\left(x^{e^{-1}}\right) = o\left(\widehat{C}_k(x)\right)$ at sufficiently large x.

Equation (3.5) becomes an ordinary differential equation for $\widehat{C}_k(x)$ with this observation. Its solution takes the form

$$\widehat{C}_k(x) = -A_0 \sqrt{2\pi} (\log x) \times \left(\int_3^x \frac{\sqrt{\log \log t}}{\log t} \times \widehat{C}'_{k,*}(t) dt \right) (1 + o(1)) + O(\log x).$$

When we integrate by parts and apply the result from Theorem 3.3, we find that

$$\widehat{C}_{k}(x) = -A_{0}\sqrt{2\pi}\sqrt{\log\log x} \times \widehat{C}_{k,*}(x) + O\left(x \times \int_{3}^{x} \frac{\sqrt{\log\log t} \times \widehat{C}_{k,*}(t)}{t^{2}(\log t)^{2}} dt\right)$$

$$= -A_{0}\sqrt{2\pi}\sqrt{\log\log x} \times \widehat{C}_{k,*}(x) + O\left(\frac{x}{2^{k}(k-1)!} \times \Gamma\left(k + \frac{1}{2}, 2\log\log x\right)\right).$$

Whenever we assume that $1 \le k \le \frac{3}{2} \log \log x$ such that $\lambda > 1$ in Proposition D.2, Theorem 3.3 implies the conclusion of the corollary.

3.2 Average order

Proof of Theorem 1.3. By Corollary 1.2 and Proposition D.2 when $\lambda = \frac{2}{3}$, we have that

$$\sum_{k=1}^{\frac{3}{2}\log\log x} \sum_{n \le x} C_{\Omega}(n) \times \sum_{k=1}^{\frac{3}{2}\log\log x} \frac{x(\log\log x)^{k-\frac{1}{2}}}{(\log x)(k-1)!} \left(1 + O\left(\frac{1}{\log\log x}\right)\right) \\
= \frac{x\sqrt{\log\log x} \times \Gamma\left(\frac{3}{2}\log\log x, \log\log x\right)}{\Gamma\left(\frac{3}{2}\log\log x\right)} \left(1 + O\left(\frac{1}{\log\log x}\right)\right) \\
= x\sqrt{\log\log x} \left(1 + O\left(\frac{1}{\log\log x}\right)\right).$$

For real $0 \le z \le 2$, the function $\widehat{G}(z)$ is monotone in z with $\widehat{G}(0) = 1$ and $\widehat{G}(2) \approx 0.303964$. Then we see that there is an absolute constant $B_0 > 0$ such that

$$\frac{1}{x} \times \sum_{k=1}^{\frac{3}{2} \log \log x} \sum_{\substack{n \le x \\ \Omega(n) = k}} C_{\Omega}(n) = B_0 \sqrt{\log \log x} \left(1 + O\left(\frac{1}{\log \log x}\right) \right).$$

We claim that

$$\frac{1}{x} \times \sum_{n \le x} C_{\Omega}(n) = \frac{1}{x} \times \sum_{k \ge 1} \sum_{\substack{n \le x \\ \Omega(n) = k}} C_{\Omega}(n)$$

$$= \frac{1}{x} \times \sum_{k=1}^{\frac{3}{2} \log \log x} \sum_{\substack{n \le x \\ \Omega(n) = k}} C_{\Omega}(n)(1 + o(1)), \text{ as } x \to \infty.$$

To prove the claim it suffices to show that

$$\frac{1}{x} \times \sum_{\substack{n \le x \\ \Omega(n) \ge \frac{3}{2} \log \log x}} C_{\Omega}(n) = o\left(\sqrt{\log \log x}\right), \text{ as } x \to \infty.$$
(3.6)

We proved in Theorem 2.2 that for all sufficiently large x and $|z| < P(2)^{-1}$

$$\sum_{n \in x} (-1)^{\omega(n)} C_{\Omega}(n) z^{\Omega(n)} = \frac{x \widehat{F}(2, z)}{\Gamma(z)} (\log x)^{z-1} + O\left(x (\log x)^{\text{Re}(z) - 2}\right).$$

By Lemma D.5, we have that the summatory function

$$\sum_{n \le x} (-1)^{\omega(n)} = \frac{(-1)^{\lfloor \log \log x \rfloor} x}{A_0 \sqrt{2\pi \log \log x}} \left(1 + O\left(\frac{1}{\sqrt{\log \log x}}\right) \right),$$

where $\frac{d}{dx} \left[\frac{x}{\sqrt{\log \log x}} \right] = \frac{1}{\sqrt{\log \log x}} + o(1)$. We can argue as in the proof of Corollary 1.2 that whenever $0 < |z| < P(2)^{-1}$ with x sufficiently large we have

$$\sum_{n \le x} C_{\Omega}(n) z^{\Omega(n)} \ll_z \frac{\widehat{F}(2, z) x \sqrt{\log \log x}}{\Gamma(z)} (\log x)^{z-1}. \tag{3.7}$$

For large x and any fixed $0 < r < P(2)^{-1}$, we define

$$\widehat{B}(x,r) \coloneqq \sum_{\substack{n \le x \\ \Omega(n) > r \log \log x}} C_{\Omega}(n).$$

We adapt the proof from the reference [18, cf. Thm. 7.20; §7.4] by applying (3.7) when $1 \le r < P(2)^{-1}$. Since $r\widehat{F}(2,r) = \frac{r\zeta(2)^{-r}}{1+P(2)r} \ll 1$ for $r \in [1, P(2)^{-1})$, and similarly since we have that $\frac{1}{\Gamma(1+r)} \gg 1$ for r within the same range, we find that

$$x\sqrt{\log\log x}(\log x)^{r-1} \gg \sum_{\substack{n \le x \\ \Omega(n) \ge r \log\log x}} C_{\Omega}(n)r^{\Omega(n)} \gg \sum_{\substack{n \le x \\ \Omega(n) \ge r \log\log x}} C_{\Omega}(n)r^{r\log\log x}.$$

This implies that for $r := \frac{3}{2}$ we have

$$\widehat{B}(x,r) \ll x(\log x)^{r-1-r\log r} \sqrt{\log\log x} = O\left(\frac{x\sqrt{\log\log x}}{(\log x)^{0.108198}}\right)$$
 (3.8)

We evaluate the limiting asymptotics of the sums

$$S_2(x) \coloneqq \frac{1}{x} \times \sum_{k \ge \frac{3}{2} \log \log x} \sum_{\substack{n \le x \\ \Omega(n) = k}} C_{\Omega}(n) \ll \frac{1}{x} \times \widehat{B}\left(x, \frac{3}{2}\right) = O\left(\frac{\sqrt{\log \log x}}{(\log x)^{0.108198}}\right), \text{ as } x \to \infty.$$

The last equation implies that (3.6) holds.

4 Properties of the function g(n)

Definition 4.1. For integers $n \ge 1$, we define the Dirichlet inverse function

$$g(n) = (\omega + 1)^{-1}(n)$$
, for $n \ge 1$.

The function |g(n)| denotes the unsigned inverse function.

Let $\chi_{\mathbb{P}}(n)$ denote the characteristic function of the primes, let $\varepsilon(n) = \delta_{n,1}$ be the multiplicative identity with respect to Dirichlet convolution, and denote by $\omega(n)$ the strongly additive function that counts the number of distinct prime factors of n (without multiplicity). We can see using elementary methods that

$$\chi_{\mathbb{P}} + \varepsilon = (\omega + 1) * \mu. \tag{4.1}$$

Namely, since $\mu * 1 = \varepsilon$ and

$$\omega(n) = \sum_{p|n} 1 = \sum_{d|n} \chi_{\mathbb{P}}(d), \text{ for } n \ge 1,$$

the result in (4.1) follows by Möbius inversion.

4.1 Signedness

Proposition 4.2. The sign of the function g(n) is $\lambda(n)$ for all $n \ge 1$.

Proof. The series $D_f(s) := \sum_{n \geq 1} f(n) n^{-s}$ defines the Dirichlet generating function (DGF) of any arithmetic function f which is convergent for all $s \in \mathbb{C}$ satisfying $\operatorname{Re}(s) > \sigma_f$ where σ_f is the abscissa of convergence of the series. Recall that $D_1(s) = \zeta(s)$, $D_{\mu}(s) = \zeta(s)^{-1}$ and $D_{\omega}(s) = P(s)\zeta(s)$ for $\operatorname{Re}(s) > 1$, where $P(s) := \sum_{n \geq 1} \chi_{\mathbb{P}}(n) n^{-s}$ denotes the prime zeta function. By (4.1) and the fact that whenever $f(1) \neq 0$, the DGF of $f^{-1}(n)$ is $D_f(s)^{-1}$, we have that

$$D_{(\omega+1)^{-1}}(s) = \frac{1}{\zeta(s)(1+P(s))}, \text{ for } \text{Re}(s) > 1.$$
 (4.2)

It follows that $(\omega + 1)^{-1}(n) = (h^{-1} * \mu)(n)$ if we take $h := \chi_{\mathbb{P}} + \varepsilon$. We first show that $\operatorname{sgn}(h^{-1}) = \lambda$. This observation implies that $\operatorname{sgn}(h^{-1} * \mu) = \lambda$ as we show by the next arguments.

By a combinatorial argument related to multinomial coefficient expansions of the DGF of h^{-1} , we recover exactly that [9, cf. §2]

$$h^{-1}(n) = \begin{cases} 1, & n = 1; \\ \lambda(n)(\Omega(n))! \times \prod_{p^{\alpha}||n} \frac{1}{\alpha!}, & n \ge 2. \end{cases}$$

In particular, notice that by expanding the DGF of h^{-1} formally in powers of P(s) (where |P(s)| < 1 whenever $Re(s) \ge 2$) we can count that

$$\frac{1}{1+P(s)} = \sum_{n\geq 1} \frac{h^{-1}(n)}{n^s} = \sum_{k\geq 0} (-1)^k P(s)^k,
= 1 + \sum_{\substack{n\geq 2\\ n=p_1^{\alpha_1} p_2^{\alpha_2} \times \dots \times p_k^{\alpha_k}}} \frac{(-1)^{\alpha_1 + \alpha_2 + \dots + \alpha_k}}{n^s} \times {\alpha_1 + \alpha_2 + \dots + \alpha_k \choose \alpha_1, \alpha_2, \dots, \alpha_k},
= 1 + \sum_{\substack{n\geq 2\\ n=p_1^{\alpha_1} p_2^{\alpha_2} \times \dots \times p_k^{\alpha_k}}} \frac{\lambda(n)}{n^s} \times {\alpha(n) \choose \alpha_1, \alpha_2, \dots, \alpha_k}.$$

Since λ is completely multiplicative we have that $\lambda\left(\frac{n}{d}\right)\lambda(d) = \lambda(n)$ for all divisors d|n when $n \ge 1$. We also know that $\mu(n) = \lambda(n)$ whenever n is squarefree so that we obtain the following results:

$$g(n) = (h^{-1} * \mu)(n) = \lambda(n) \times \sum_{d|n} \mu^2 \left(\frac{n}{d}\right) |h^{-1}(n)|, n \ge 1.$$

4.2 Precise relations to $C_{\Omega}(n)$

The computational data given in the tables from Appendix F is reproduced to motivate the exact formulas for g(n) proved in this section. The tables provide illustrative numerical data by examining the first cases of $1 \le n \le 500$. The formula exactly expanding $C_{\Omega}(n)$ by finite products in (1.3) shows that its values are determined completely by the *exponents* alone in the prime factorization of any $n \ge 2$, e.g., this function is factorization symmetric in the sense of Definition 1.1.

Lemma 4.3. For all $n \ge 1$, we have that

$$g(n) = \sum_{d|n} \mu\left(\frac{n}{d}\right) \lambda(d) C_{\Omega}(d).$$

Proof. We first expand the recurrence relation for the Dirichlet inverse when $g(1) = g(1)^{-1} = 1$ as

$$g(n) = -\sum_{\substack{d|n\\d>1}} (\omega(d) + 1)g\left(\frac{n}{d}\right) \quad \Longrightarrow \quad (g*1)(n) = -(\omega*g)(n). \tag{4.3}$$

We argue that for $1 \le m \le \Omega(n)$, we can inductively expand the implication on the right-hand-side of (4.3) in the form of $(g * 1)(n) = F_m(n)$ where $F_m(n) := (-1)^m (C_m(-) * g)(n)$, so that

$$F_{m}(n) = -\begin{cases} (\omega * g)(n), & m = 1; \\ \sum\limits_{\substack{d \mid n \\ d > 1}} F_{m-1}(d) \times \sum\limits_{\substack{r \mid \frac{n}{d} \\ r > 1}} \omega(r) g\left(\frac{n}{dr}\right), & 2 \le m \le \Omega(n); \\ 0, & \text{otherwise.} \end{cases}$$

When $m := \Omega(n)$, i.e., with the expansions in the previous equation taken to a maximal depth, we obtain the relation

$$(g * 1)(n) = (-1)^{\Omega(n)} C_{\Omega}(n) = \lambda(n) C_{\Omega}(n). \tag{4.4}$$

The stated formula for g(n) follows from (4.4) by Möbius inversion.

Corollary 4.4. For all positive integers $n \ge 1$, we have that

$$|g(n)| = \sum_{d|n} \mu^2 \left(\frac{n}{d}\right) C_{\Omega}(d). \tag{4.5}$$

Proof. By applying Lemma 4.3, Proposition 4.2 and the complete multiplicativity of $\lambda(n)$, we easily obtain the stated result. In particular, since $\mu(n)$ is non-zero only at squarefree integers and since at any squarefree $d \ge 1$ we have $\mu(d) = (-1)^{\omega(d)} = \lambda(d)$, Lemma 4.3 and Proposition 4.2 imply that

$$|g(n)| = \lambda(n) \times \sum_{d|n} \mu\left(\frac{n}{d}\right) \lambda(d) C_{\Omega}(d)$$
$$= \lambda(n^{2}) \times \sum_{d|n} \mu^{2}\left(\frac{n}{d}\right) C_{\Omega}(d).$$

We see that that $\lambda(n^2) = +1$ for all $n \ge 1$ since the number of distinct prime factors (counting multiplicity) of any square integer is even.

The formula in (4.5) shows that the DGF of the unsigned inverse function, |g(n)|, is given by the meromorphic function $\frac{1}{\zeta(2s)(1-P(s))}$ for all $s \in \mathbb{C}$ with Re(s) > 1. This DGF has a known pole to the right of the line at Re(s) = 1 which occurs for the unique real $\sigma \equiv \sigma_1 \approx 1.39943$ such that $P(\sigma) = 1$ on $(1, +\infty)$.

We have that whenever $n \ge 1$ is squarefree

$$|g(n)| = \sum_{d|n} C_{\Omega}(d).$$

Since all divisors of a squarefree integer are squarefree, a proof of part (B) of Proposition 1.5 follows by a counting argument as a consequence of the previous equation.

4.3 Average order

Proof of Corollary 1.4. As $|z| \to \infty$, the imaginary error function, erfi(z), has the following asymptotic series expansion [24, §7.12]:

$$\operatorname{erfi}(z) := \frac{2}{\sqrt{\pi i}} \times \int_0^{iz} e^{t^2} dt = \frac{e^{z^2}}{\sqrt{\pi}} \left(\frac{1}{z} + \frac{1}{2z^3} + \frac{3}{4z^5} + \frac{15}{8z^7} + O\left(\frac{1}{z^9}\right) \right). \tag{4.6}$$

We use the formula from Theorem 1.3 to sum the average order of $C_{\Omega}(n)$. The proposition and error terms obtained from (4.6) imply that for all sufficiently large $t \to \infty$

$$\int \frac{\sum_{n \le t} C_{\Omega}(n)}{t^2} dt = B_0(\log t) \sqrt{\log \log t} - \frac{B_0 \sqrt{\pi}}{2} \operatorname{erfi}\left(\sqrt{\log \log t}\right)$$
$$= B_0(\log t) \sqrt{\log \log t} \left(1 + O\left(\frac{1}{\log \log t}\right)\right). \tag{4.7}$$

A classical formula for the summatory function that counts the number of squarefree integers $n \le x$ shows that this function satisfies [10, §18.6] [27, A013928]

$$Q(x) = \sum_{n \le x} \mu^2(n) = \frac{6x}{\pi^2} + O\left(\sqrt{x}\right), \text{ as } x \to \infty.$$

Therefore, summing over the formula from (4.5) in Section 4.2, we find that

$$\frac{1}{n} \times \sum_{k \le n} |g(k)| = \frac{1}{n} \times \sum_{d \le n} C_{\Omega}(d) Q\left(\left\lfloor \frac{n}{d} \right\rfloor\right)$$

$$\sim \sum_{d \le n} C_{\Omega}(d) \left(\frac{6}{d \cdot \pi^2} + O\left(\frac{1}{\sqrt{dn}}\right)\right)$$

$$= \frac{6}{\pi^2} \left(\frac{1}{n} \times \sum_{k \le n} C_{\Omega}(k) + \sum_{d \le n} \sum_{k \le d} \frac{C_{\Omega}(k)}{d^2}\right) + O(1).$$

The latter sum in the previous equation forms the main term that we approximate using the asymptotics for the integral in (4.7) for all large enough t as $t \to \infty$.

5 Conjectured Erdős-Kac theorem analogs for the unsigned sequences

The average order of $C_{\Omega}(n)$ is given by Theorem 1.3. We can show that the second moment type partial sums of the deterministic function $C_{\Omega}(n)$ satisfy

$$\frac{1}{n} \times \left(\sum_{k \le n} C_{\Omega}(k)^2 - \left(\sum_{k \le n} C_{\Omega}(k) \right)^2 \right) = \frac{2}{n} \times \sum_{1 \le j < k \le n} C_{\Omega}(j) C_{\Omega}(k),$$
$$= B_0^2 n (\log \log n) (1 + o(1)), \text{ as } n \to \infty.$$

This calculation leads to the next conjectured result. Rigorous proofs of the conjectured results below are outside of the scope of this manuscript.

Conjecture 5.1 (Deterministic form of an Erdős-Kac theorem analog for $C_{\Omega}(n)$). There is a limiting probability measure on \mathbb{R} with CDF Φ_{Ω} such that for any real z

$$\frac{1}{x} \times \# \left\{ 3 \le n \le x : \frac{C_{\Omega}(n) - B_0 \sqrt{\log \log \log x}}{B_0 \sqrt{(\log x)(\log \log \log x)}} \le z \right\} = \Phi_{\Omega}(z) + o(1), \text{ as } x \to \infty$$

Corollary 5.2. Suppose that Conjecture 5.1 is true and that the function Φ_{Ω} is defined as in the conjecture. For any real y, as $x \to \infty$

$$\frac{1}{x} \times \# \left\{ 3 \le n \le x : \frac{|g(n)| - \frac{6}{\pi^2 n} \times \sum_{k \le n} |g(k)| - B_0 \sqrt{\log \log \log x}}{B_0 \sqrt{(\log x)(\log \log \log x)}} \le y \right\} = \Phi_{\Omega} \left(\frac{\pi^2 y}{6} \right) + o(1).$$

Proof. We claim that

$$|g(n)| - \frac{6}{\pi^2 n} \times \sum_{k \le n} |g(k)| \sim \frac{6}{\pi^2} C_{\Omega}(n)$$
, as $n \to \infty$.

As in the proof of Corollary 1.4, we obtain that

$$\frac{1}{x} \times \sum_{n \le x} |g(n)| = \frac{6}{\pi^2} \left(\frac{1}{x} \times \sum_{n \le x} C_{\Omega}(n) + \sum_{d < x} \sum_{k \le d} \frac{C_{\Omega}(k)}{d^2} \right) + O(1).$$

Let the backwards difference operator with respect to x be defined for $x \ge 2$ and any arithmetic function f as $\Delta_x[f] := f(x) - f(x-1)$. We see that for large n

$$|g(n)| = \Delta_n \left[\sum_{k \le n} g(k) \right] \sim \frac{6}{\pi^2} \times \Delta_n \left[\sum_{d \le n} C_{\Omega}(d) \frac{n}{d} \right]$$

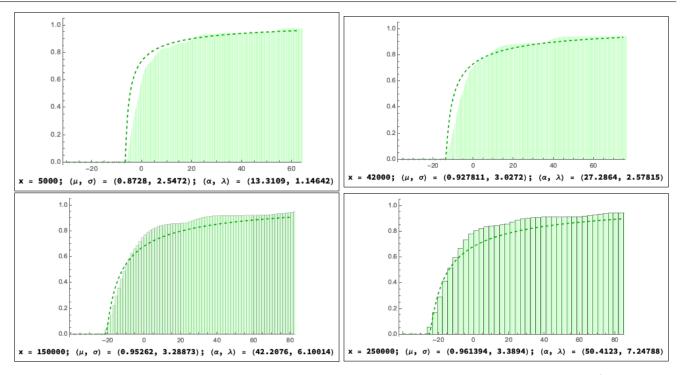

Figure 5.1: Histograms representing the CDF of the distribution of $\sigma^{-1}\left(|g(n)| - \frac{6}{\pi^2 n} \times \sum_{k \le n} |g(k)| - \frac{6\mu}{\pi^2}\right)$ for $n \le x$ where $\mu \equiv \mu(x) = \sqrt{\log\log\log x}$ and $\sigma \equiv \sigma(x) = \sqrt{(\log x)(\log\log\log x)}$. The dashed line shows a the CDF of the fit of an inverse Gaussian distribution with mean α and scale parameter λ .

$$= \frac{6}{\pi^2} \left(C_{\Omega}(n) + \sum_{d < n} C_{\Omega}(d) \frac{n}{d} - \sum_{d < n} C_{\Omega}(d) \frac{(n-1)}{d} \right)$$
$$\sim \frac{6}{\pi^2} \left(C_{\Omega}(n) + \frac{1}{n-1} \times \sum_{k < n} |g(k)| \right), \text{ as } n \to \infty.$$

Since $\frac{1}{n-1} \times \sum_{k \le n} |g(k)| \sim \frac{1}{n} \times \sum_{k \le n} |g(k)|$ for all sufficiently large n by Corollary 1.4, the result follows by a re-normalization of Conjecture 5.1.

6 New exact formulas for M(x)

6.1 Formulas relating M(x) to the summatory function G(x)

Definition 6.1. The summatory function of g(n) is defined for all $x \ge 1$ by the partial sums

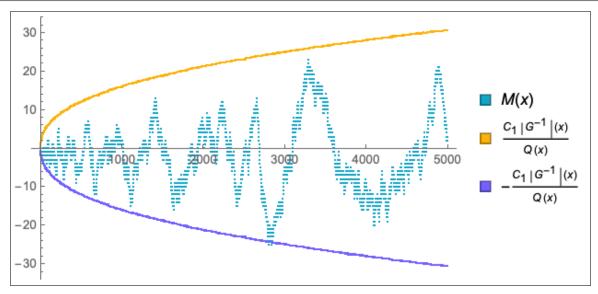

$$G(x) := \sum_{n \le x} g(n) = \sum_{n \le x} \lambda(n) |g(n)|.$$
 (6.1a)

Let the corresponding unsigned partial sums be defined for $x \ge 1$ by

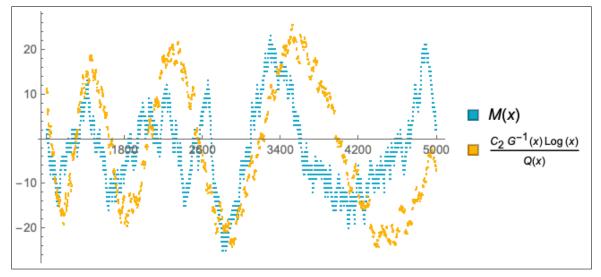

$$|G|(x) \coloneqq \sum_{n \le r} |g(n)|. \tag{6.1b}$$

A key consequence of Theorem E.1 (proved in the appendix) as it applies to M(x) in the special cases where $h(n) := \mu(n)$ for all $n \ge 1$ is stated in the next corollary.

Corollary 6.2 (Applications of Möbius inversion). Suppose that r is an arithmetic function such that $r(1) \neq 0$. Let the summatory function of the convolution of r with μ be defined by $\widetilde{R}(x) := \sum_{n \leq x} (r * \mu)(n)$.

(a) Numerically bounded envelopes for the local extremum of M(x) expressed in terms of the partial sums of the unsigned inverse function. The value of the scaling factor C_1 is chosen to be the absolute constant $C_1 := \frac{1}{\zeta(2)}$.

(b) A comparison of M(x) and a scaled form of G(x) where the absolute constant $C_2 := \zeta(2)$.

Figure 6.1: Discrete plots displaying comparisons of the growth of M(x) to the new auxillary partial sums for $x \le 5000$. The scaling function $Q(x) := \sum_{n \le x} \mu^2(n)$ counts the number of squarefree integers $n \le x$ for any $x \ge 1$.

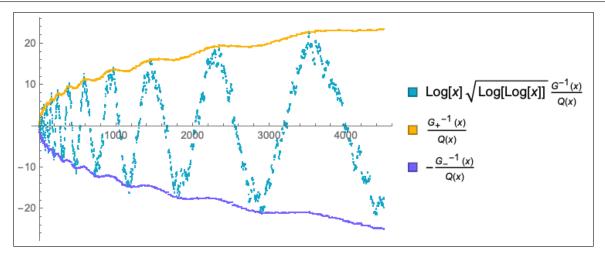

The Mertens function is expressed by the partial sums

$$M(x) = \sum_{k=1}^{x} \left(\sum_{j=\left|\frac{x}{k+1}\right|+1}^{\left\lfloor\frac{x}{k}\right\rfloor} r^{-1}(j) \right) \widetilde{R}(k), \text{ for } x \ge 1.$$

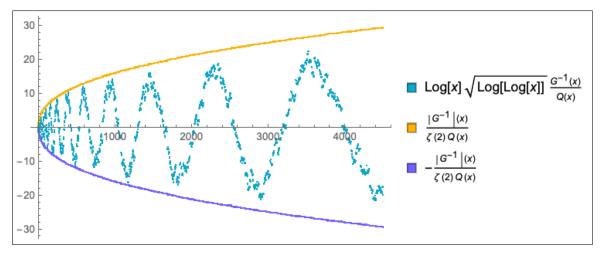

Based on the convolution identity given in (4.1), we can prove the formulas in Theorem 1.6 as special cases of Corollary 6.2.

Proof of (1.6a) and (1.6b) in Theorem 1.6. We know by applying Theorem E.1 to equation (4.1) that

$$M(x) = \sum_{k=1}^{x} g(k) \left(\pi \left(\left\lfloor \frac{x}{k} \right\rfloor \right) + 1 \right)$$

(a) Comparisons of a logarithmically scaled form of G(x) and envelopes that bound its local extremum given by sign-weighted components that contribute to these partial sums. Namely, we define $G(x) := G_+(x) - G_-(x)$ where the functions $G_+(x) > 0$ and $G_-(x) > 0$ for all $x \ge 1$ so that these signed component functions denote the unsigned contributions of only those summands |g(n)| over $n \le x$ such that $\lambda(n) = \pm 1$, respectively.

(b) Comparisions of bounded envelopes for the local extremum of the logarithmically scaled values of G(x) to the absolute values of the partial sums of the scaled unsigned inverse function.

Figure 6.2: Discrete plots displaying comparisons of the growth of G(x) to the new auxillary partial sums for $x \le 4500$. The scaling function $Q(x) := \sum_{n \le x} \mu^2(n)$ counts the number of squarefree integers $n \le x$ for any $x \ge 1$.

$$= G(x) + \sum_{k=1}^{\frac{x}{2}} g(k) \pi \left(\left\lfloor \frac{x}{k} \right\rfloor \right)$$

$$= G(x) + G\left(\left\lfloor \frac{x}{2} \right\rfloor \right) + \sum_{k=1}^{\frac{x}{2}-1} G(k) \left(\pi \left(\left\lfloor \frac{x}{k} \right\rfloor \right) - \pi \left(\left\lfloor \frac{x}{k+1} \right\rfloor \right) \right).$$

The upper bound on the sum is truncated to $k \in [1, \frac{x}{2}]$ in the second equation above due to the fact that $\pi(1) = 0$. The third formula above follows directly by (ordinary) summation by parts.

Proof of (1.6c) in Theorem 1.6. Lemma 4.3 shows that the summatory function of g(n) satisfies

$$G(x) = \sum_{d \le x} \lambda(d) C_{\Omega}(d) M\left(\left\lfloor \frac{x}{d} \right\rfloor\right).$$

The identity in equation (4.1) implies that

$$\lambda(d)C_{\Omega}(d) = (g * 1)(d) = (\chi_{\mathbb{P}} + \varepsilon)^{-1}(d).$$

We recover the stated result by classical inversion of summatory functions.

Bounds on the partial sums over the unsigned inverse functions in (6.1b) provide some local information on G(x) through its connection with |G|(x). The plots shown in Figure 6.1 and Figure 6.2 compare the values of M(x) and G(x) with scaled forms of auxilliary partial sums related to the expansion of the latter summatory function.

6.2 Example: Local cancellation of G(x) in the new formulas for M(x)

Definition 6.3. Suppose that p_n denotes the n^{th} prime for $n \ge 1$ [27, $\underline{A000040}$]. Let $\mathcal{P}_{\#}$ denote the set of primorial integers given by [27, $\underline{A002110}$]

$$\mathcal{P}_{\#} = \{n\#\}_{n\geq 1} = \left\{\prod_{k=1}^{n} p_k : n \geq 1\right\}.$$

Proposition 6.4. As $m \to \infty$ we have that

$$-G((4m+1)\#) \approx (4m+1)!,$$
 (A)

$$G\left(\frac{(4m+1)\#}{p_k}\right) \approx (4m)!, \text{ for any } 1 \le k \le 4m+1.$$
 (B)

Proof. We have by part (B) of Proposition 1.5 that for all squarefree integers $n \ge 1$

$$|g(n)| = \sum_{j=0}^{\omega(n)} {\omega(n) \choose j} \times j! = (\omega(n))! \times \sum_{j=0}^{\omega(n)} \frac{1}{j!}$$
$$= (\omega(n))! \times \left(e + O\left(\frac{1}{(\omega(n) + 1)!}\right) \right).$$

Let m be a large positive integer. We obtain main terms of the form

$$\sum_{\substack{n \le (4m+1)\#\\ \omega(n) = \Omega(n)}} \lambda(n)|g(n)| = \sum_{0 \le k \le 4m+1} {4m+1 \choose k} (-1)^k k! \left(e + O\left(\frac{1}{(k+1)!}\right) \right)$$

$$= -(4m+1)! + O(1).$$
(6.2)

The formula for $C_{\Omega}(n)$ stated in (1.3) then implies the result in (A). This follows since the contributions from the summands of the inner summation on the right-hand-side of (6.2) off of the squarefree integers are at most a bounded multiple of $(-1)^k k!$ when $\Omega(n) = k$ by the cited formula. We can similarly derive for any $1 \le k \le 4m + 1$ that

$$G\left(\frac{(4m+1)\#}{p_k}\right) \times \sum_{0 \le k \le 4m} {4m \choose k} (-1)^k k! \left(e + O\left(\frac{1}{(k+1)!}\right)\right) \times (4m)!.$$

Remark 6.5. We expect that there is usually (almost always) a large amount cancellation between the successive values of this summatory function in the form of (1.6c). Proposition 6.4 demonstrates the phenomenon well along the infinite subsequence of large x taken along the primorials, $\{(4m+1)\#\}_{m>1}$.

The RH requires that the sums of the leading constants with opposing signs on the asymptotics for the functions from the lemma match. In particular, we have that [6, 7]

$$n# \sim e^{\vartheta(p_n)} \approx n^n (\log n)^n e^{-n(1+o(1))}$$
, as $n \to \infty$.

Indeed, this observation follows from the fact that if we obtain a contrary result, equation (1.6c) would imply that

$$\frac{M((4m+1)\#)}{\sqrt{(4m+1)\#}} \gg [(4m+1)\#]^{\delta_0}, \text{ as } m \to \infty,$$

for some fixed $\delta_0 > 0$ (cf. equation (B.1) of the appendix).

7 Conclusions

We have identified a new sequence, $\{g(n)\}_{n\geq 1}$, that is the Dirichlet inverse of the shifted strongly additive function $\omega(n)$. We showed that there is a natural (factorization symmetric) combinatorial interpretation to the distribution of distinct values of |g(n)| for $n \leq x$ tied the distribution of the primes $p \leq x$. The sign of g(n) is given by $\lambda(n)$ for all $n \geq 1$. This leads to a new exact relations of the summatory function G(x) to M(x) and the classical summatory function L(x). In the process of studying the unsigned sequences $C_{\Omega}(n)$ and |g(n)|, we have formalized a probabilistic perspective from which to express our intuition about features of the distribution of G(x) via the properties of its $\lambda(n)$ -sign-weighted summands |g(n)| for $n \leq x$. We emphasize that our new work on the Mertens function proved within this article is significant in providing a new window through which we can view bounding M(x) through asymptotics of the auxiliary sequences and partial sums. The computational data generated in Table F of the appendix section is numerically suggestive that the distribution of G(x) is easier to work with than that of M(x) or L(x) directly.

We expect that an outline of the method behind the collective proofs we provide with respect to the Mertens function case can be generalized to identify associated strongly additive functions with the same role of $\omega(n)$ in this article. We expect that natural extensions exist in connection with the signed Dirichlet inverse of any arithmetic f > 0 and its partial sums. The link between strong additivity and resulting sequences to express the partial sums of signed Dirichlet inverse functions are computationally useful in more efficiently computing all of the first $x \ge 3$ values of these summatory functions when x is large.

Acknowledgments

We thank the following professors that offered discussion, feedback and correspondence while the article was being actively written: Gergő Nemes, Jeffrey Lagarias, Robert Vaughan, Steven J. Miller, Paul Pollack and Bruce Reznick. The work on the article was supported in part by funding made available within the School of Mathematics at the Georgia Institute of Technology in 2020 and 2021. Without this combined support, the article would not have been possible.

A Glossary of notation and conventions

The next listing provides a mostly comprehensive glossary of common notation, conventions and abbreviations used in the article.

Symbols	Definition
≫,≪,≍,∼	For functions A, B , the notation $A \ll B$ implies that $A = O(B)$. Similarly, for $B \ge 0$ the notation $A \gg B$ implies that $B = O(A)$. When we have that $A, B \ge 0$, $A \ll B$ and $B \ll A$, we write $A \times B$. Two arithmetic functions $A(x), B(x)$ satisfy the relation $A \sim B$ if $\lim_{x \to \infty} \frac{A(x)}{B(x)} = 1$.
$\chi_{\mathbb{P}}(n), P(s)$	The indicator function of the primes equals one if and only if $n \in \mathbb{Z}^+$ is prime and is defined to be zero-valued otherwise. For any $s \in \mathbb{C}$ such that $\text{Re}(s) > 1$, we define the prime zeta function to be the Dirichlet generating function (DGF) defined by $P(s) = \sum_{n \geq 1} \frac{\chi_{\mathbb{P}}(n)}{n^s}$. The function $P(s)$ has an
	analytic continuation to the half-plane $\operatorname{Re}(s) > 0$ with the exception of $s = 1$ through the formula $P(s) = \sum_{k>1} \frac{\mu(k)}{k} \log \zeta(ks)$. The DGF $P(s)$ poles
	at the reciprocal of each positive integer and a natural boundary at the line $Re(s) = 0$.
$C_k(n), C_{\Omega}(n)$	The first sequence is defined recursively for integers $n \ge 1$ and $k \ge 0$ as follows:
	$C_k(n) := \begin{cases} \delta_{n,1}, & \text{if } k = 0; \\ \sum_{d n} \omega(d) C_{k-1} \left(\frac{n}{d}\right), & \text{if } k \ge 1. \end{cases}$
	It represents the multiple $(k\text{-fold})$ convolution of the function $\omega(n)$ with itself. The function $C_{\Omega}(n) := C_{\Omega(n)}(n)$ has the DGF $(1 - P(s))^{-1}$ for $\text{Re}(s) > 1$.
$[q^n]F(q)$	The coefficient of q^n in the power series expansion of $F(q)$ about zero when $F(q)$ is treated as the ordinary generating function (OGF) of a sequence, $\{f_n\}_{n\geq 0}$. Namely, for integers $n\geq 0$ we define $[q^n]F(q)=f_n$ whenever $F(q):=\sum_{n\geq 0}f_nq^n$.
arepsilon(n)	The multiplicative identity with respect to Dirichlet convolution, $\varepsilon(n) := \delta_{n,1}$, defined such that for any arithmetic function f we have that $f * \varepsilon = \varepsilon * f = f$ where the operation $*$ denotes Dirichlet convolution.
f * g	The Dirichlet convolution of any two arithmetic functions f and g at n is defined to be the divisor sum $(f * g)(n) := \sum_{d n} f(d)g\left(\frac{n}{d}\right)$ for $n \ge 1$.
$f^{-1}(n)$	The Dirichlet inverse f^{-1} of an arithmetic function f exists if and only if $f(1) \neq 0$. The Dirichlet inverse of any f such that $f(1) \neq 0$ is defined recursively by $f^{-1}(n) = -\frac{1}{f(1)} \times \sum_{\substack{d \mid n \\ d > 1}} f(d) f^{-1}\left(\frac{n}{d}\right)$ for $n \geq 2$ with $f^{-1}(1) = 0$
	$f(1)^{-1}$. When it exists, this inverse function is unique and satisfies $f^{-1} * f = f * f^{-1} = \varepsilon$.
$\Gamma(a,z)$	The incomplete gamma function is defined as $\Gamma(a,z) := \int_z^\infty t^{a-1}e^{-t}dt$ by continuation for $a \in \mathbb{R}$ and $ \arg(z) < \pi$. Asymptotics of this function as both $a, z \to \infty$ independently are discussed in the appendix.

Symbols	Definition
$\mathcal{G}(z),\widetilde{\mathcal{G}}(z);\ \widehat{F}(s,z),\widehat{\mathcal{G}}(z)$	The functions $\mathcal{G}(z)$ and $\widetilde{\mathcal{G}}(z)$ are defined for $0 \leq z \leq R < 2$ on page 26 of Appendix C. The related constructions used to motivate the definitions of $\widehat{F}(s,z)$ and $\widehat{\mathcal{G}}(z)$ are defined by the infinite products over the primes given on pages 5 and 8 of Section 3.1, respectively.
g(n), G(x), G (x)	The Dirichlet inverse function, $g(n) = (\omega + 1)^{-1}(n)$, has the summatory function $G(x) := \sum_{n \le x} g(n)$ for $x \ge 1$. We define the partial sums of the
	unsigned inverse function to be $ G (x) := \sum_{n \le x} g(n) $ for $x \ge 1$.
$[n=k]_{\delta},[{ t cond}]_{\delta}$	The symbol $[n = k]_{\delta}$ is a synonym for $\delta_{n,k}$ which is one if and only if $n = k$, and is zero otherwise. For Boolean-valued conditions, cond, the symbol $[cond]_{\delta}$ evaluates to one precisely when cond is true or to zero otherwise.
$\lambda(n), L(x)$	The Liouville lambda function is the completely multiplicative function defined by $\lambda(n) := (-1)^{\Omega(n)}$. Its summatory function is defined by the partial sums $L(x) := \sum_{n \le x} \lambda(n)$ for $x \ge 1$.
$\mu(n), M(x)$	The Möbius function defined such that $\mu^2(n)$ is the indicator function of the squarefree integers $n \ge 1$ where $\mu(n) = (-1)^{\omega(n)}$ whenever n is squarefree. The Mertens function is the summatory function defined for all integers $x \ge 1$ by the partial sums $M(x) := \sum_{n \le x} \mu(n)$.
$\omega(n),\Omega(n)$	We define the strongly additive function $\omega(n) := \sum_{p n} 1$ and the completely additive function $\Omega(n) := \sum_{p^{\alpha} n} \alpha$. This means that if the prime factorization of any $n \geq 2$ is given by $n := p_1^{\alpha_1} \times \cdots \times p_r^{\alpha_r}$ with $p_i \neq p_j$ for all $i \neq j$, then
	$\omega(n) = r$ and $\Omega(n) = \alpha_1 + \dots + \alpha_r$. We set $\omega(1) = \Omega(1) = 0$ by convention.
$\pi_k(x), \widehat{\pi}_k(x)$	For integers $k \geq 1$, the function $\pi_k(x)$ denotes the number of $2 \leq n \leq x$ with exactly k distinct prime factors: $\pi_k(x) := \#\{2 \leq n \leq x : \omega(n) = k\}$. Similarly, the function $\widehat{\pi}_k(x) := \#\{2 \leq n \leq x : \Omega(n) = k\}$ for $x \geq 2$ and fixed $k \geq 1$.
Q(x)	For $x \ge 1$, we define $Q(x)$ to be the summatory function indicating the number of squarefree integers $n \le x$. That is, $Q(x) := \sum_{n \le x} \mu^2(n)$ where
	$Q(x) = \frac{6x}{\pi^2} + O(\sqrt{x}).$
W(x)	For $x, y \in [0, +\infty)$, we write that $x = W(y)$ if and only if $xe^x = y$. This function denotes the principal branch of the multi-valued Lambert W function taken over the non-negative reals.
$\zeta(s)$	The Riemann zeta function is defined by $\zeta(s) := \sum_{n>1} n^{-s}$ when $\text{Re}(s) > 1$,
	and by analytic continuation to any $s \in \mathbb{C}$ with the exception of a simple

B The Mertens function

An approach to evaluating the behavior of M(x) for large $x \to \infty$ considers an inverse Mellin transform of the reciprocal of the Riemann zeta function given by

pole at s = 1 of residue one.

$$\frac{1}{\zeta(s)} = \prod_{p} \left(1 - \frac{1}{p^s} \right) = s \times \int_1^{\infty} \frac{M(x)}{x^{s+1}} dx, \text{ for } \operatorname{Re}(s) > 1.$$

We then obtain the following contour integral representation of M(x) for $x \ge 1$:

$$M(x) = \lim_{T \to \infty} \frac{1}{2\pi i} \times \int_{T - i\infty}^{T + i\infty} \frac{x^s}{s\zeta(s)} ds.$$

The previous formulas lead to the exact expression of M(x) for any x > 0 given by the next theorem.

Theorem B.1 (Titchmarsh). Assuming the Riemann Hypothesis (RH), there exists an infinite sequence $\{T_k\}_{k\geq 1}$ satisfying $k\leq T_k\leq k+1$ for each integer $k\geq 1$ such that for any x>0

$$M(x) = \lim_{k \to \infty} \sum_{\substack{\rho: \zeta(\rho) = 0 \\ 0 < |\operatorname{Im}(\rho)| < T_k}} \frac{x^{\rho}}{\rho \zeta'(\rho)} + \sum_{n \ge 1} \frac{(-1)^{n-1}}{n(2n)! \zeta(2n+1)} \left(\frac{2\pi}{x}\right)^{2n} + \frac{\mu(x)}{2} \left[x \in \mathbb{Z}^+\right]_{\delta} - 2.$$

An unconditional bound on the Mertens function due to Walfisz (circa 1963) states that there is an absolute constant $C_1 > 0$ such that

 $M(x) \ll x \times \exp\left(-C_1 \log^{\frac{3}{5}}(x) (\log \log x)^{-\frac{1}{5}}\right).$

Under the assumption of the RH, Soundararajan and Humphries, respectively, improved estimates bounding M(x) from above for large x in the following forms [28, 11]:

$$M(x) \ll \sqrt{x} \times \exp\left(\sqrt{\log x}(\log\log x)^{14}\right),$$

 $M(x) \ll \sqrt{x} \times \exp\left(\sqrt{\log x}(\log\log x)^{\frac{5}{2}+\epsilon}\right), \text{ for all } \epsilon > 0.$

The RH is equivalent to showing that

$$M(x) = O\left(x^{\frac{1}{2} + \epsilon}\right)$$
, for all $0 < \epsilon < \frac{1}{2}$. (B.1)

There is a rich history to the original statement of the Mertens conjecture which asserts that $|M(x)| < C_2\sqrt{x}$ for an absolute constant $C_2 > 0$. The conjecture was first verified by F. Mertens himself for $C_2 = 1$ at all $x < 10^4$ without the benefit of modern computation. Since its beginnings in 1897, the Mertens conjecture was disproved by computational methods involving non-trivial simple zeta function zeros with comparatively small imaginary parts in the famous paper by Odlyzko and te Riele [23].

More recent attempts at bounding M(x) naturally consider determining the rates at which the scaled function $M(x)x^{-\frac{1}{2}}$ grows with or without bound along infinite subsequences, e.g., considering the asymptotics of the function in the limit supremum and limit infimum senses. It is so far verified by computation that $[26, cf. \S4.1]$ [27, cf. A051400; A051401]

$$\overline{L} := \limsup_{x \to \infty} \frac{M(x)}{\sqrt{x}} > 1.060$$
 (more recently $\overline{L} \ge 1.826054$),

and

$$\underline{L} := \liminf_{x \to \infty} \frac{M(x)}{\sqrt{x}} < -1.009$$
 (more recently $\underline{L} \le -1.837625$).

Computational tractability has so far been a significant barrier to proving better bounds on these two limiting quantities on modern computers. Based on the work by Odlyzko and te Riele (circa 1985), it is still widely believed that these limiting bounds evaluate to $\pm \infty$, respectively [23, 15, 16, 12]. A conjecture due to Gonek asserts that in fact M(x) satisfies [22]

$$\limsup_{x \to \infty} \frac{|M(x)|}{\sqrt{x}(\log \log \log x)^{\frac{5}{4}}} = C_3,$$

for $C_3 > 0$ an absolute constant.

C The distributions of $\omega(n)$ and $\Omega(n)$

The next theorems reproduced from [18, §7.4] demonstrate the relative scarcity of the distributions of $\omega(n)$ and $\Omega(n)$ for $n \leq x$ such that $\omega(n)$, $\Omega(n) < \log \log x$ and $\omega(n)$, $\Omega(n) > \log \log x$. Since $\frac{1}{n} \times \sum_{k \leq n} \omega(k) = \log \log n + B_1 + o(1)$ and $\frac{1}{n} \times \sum_{k \leq n} \Omega(k) = \log \log n + B_2 + o(1)$ for $B_1 \approx 0.261497$ and $B_2 \approx 1.03465$ absolute constants in each case [10, §22.10], these results imply a distinctively regular tendency of these strongly additive arithmetic functions towards their respective average orders.

Theorem C.1 (Upper bounds on exceptional values of $\Omega(n)$ for large n). For $x \ge 2$ and r > 0, let

$$A(x,r) := \# \{ n \le x : \Omega(n) \le r \log \log x \},$$

 $B(x,r) := \# \{ n \le x : \Omega(n) \ge r \log \log x \}.$

If $0 < r \le 1$, then

$$A(x,r) \ll x(\log x)^{r-1-r\log r}$$
, as $x \to \infty$.

If $1 \le r \le R < 2$, then

$$B(x,r) \ll_R x(\log x)^{r-1-r\log r}$$
, as $x \to \infty$.

Theorem C.2 is a special case analog of the Erdős-Kac theorem for the normally distributed values of $\frac{\omega(n) - \log \log n}{\sqrt{\log \log n}}$ over $n \le x$ as $x \to \infty$ [18, cf. Thm. 7.21] [14, cf. §1.7].

Theorem C.2. We have that as $x \to \infty$

$$\# \{3 \le n \le x : \Omega(n) \le \log \log n\} = \frac{x}{2} + O\left(\frac{x}{\sqrt{\log \log x}}\right).$$

Theorem C.3 (Montgomery and Vaughan). Recall that for integers $k \ge 1$ and $x \ge 2$ we have defined

$$\widehat{\pi}_k(x) := \#\{2 \le n \le x : \Omega(n) = k\}.$$

For 0 < R < 2 we have uniformly for all $1 \le k \le R \log \log x$ that

$$\widehat{\pi}_k(x) = \frac{x}{\log x} \times \mathcal{G}\left(\frac{k-1}{\log\log x}\right) \frac{(\log\log x)^{k-1}}{(k-1)!} \left(1 + O_R\left(\frac{k}{(\log\log x)^2}\right)\right),$$

where

$$\mathcal{G}(z) \coloneqq \frac{1}{\Gamma(1+z)} \times \prod_{p} \left(1 - \frac{z}{p}\right)^{-1} \left(1 - \frac{1}{p}\right)^{z}, 0 \le |z| < R.$$

Remark C.4. We can extend the work in [18] on the distribution of $\Omega(n)$ to obtain corresponding analogous results for the distribution of $\omega(n)$. For 0 < R < 2 we have that as $x \to \infty$

$$\pi_k(x) = \frac{x}{\log x} \times \widetilde{\mathcal{G}}\left(\frac{k-1}{\log\log x}\right) \frac{(\log\log x)^{k-1}}{(k-1)!} \left(1 + O_R\left(\frac{k}{(\log\log x)^2}\right)\right),\tag{C.1}$$

uniformly for any $1 \le k \le R \log \log x$. The factors of the function $\widetilde{\mathcal{G}}(z)$ used to express these bounds are defined by $\widetilde{\mathcal{G}}(z) := \widetilde{F}(1,z) \times \Gamma(1+z)^{-1}$ where

$$\widetilde{F}(s,z) \coloneqq \prod_{p} \left(1 + \frac{z}{p^s - 1}\right) \left(1 - \frac{1}{p^s}\right)^z, \operatorname{Re}(s) > \frac{1}{2}, |z| \le R < 2.$$

Let the functions

$$C(x,r) := \#\{n \le x : \omega(n) \le r \log \log x\},\$$

 $D(x,r) := \#\{n \le x : \omega(n) \ge r \log \log x\}.$

We have the following upper bounds that hold as $x \to \infty$:

$$C(x,r) \ll x(\log x)^{r-1-r\log r}$$
, uniformly for $0 < r \le 1$,
 $D(x,r) \ll_R x(\log x)^{r-1-r\log r}$, uniformly for $1 \le r \le R < 2$.

D Partial sums expressed in terms of the incomplete gamma function

We appreciate the correspondence with Gergő Nemes from the Alfréd Rényi Institute of Mathematics and his careful notes on the limiting asymptotics for the sums identified in this section. We have adapted the communication of his proofs to establish the next few lemmas based on his recent work in the references [19, 20, 21].

Facts D.1 (The incomplete gamma function). The (upper) incomplete gamma function is defined by [24, §8.4]

 $\Gamma(a,z) = \int_{-\infty}^{\infty} t^{a-1} e^{-t} dt, a \in \mathbb{R}, |\arg z| < \pi.$

The function $\Gamma(a, z)$ can be continued to an analytic function of z on the universal covering of $\mathbb{C}\setminus\{0\}$. For $a \in \mathbb{Z}^+$, the function $\Gamma(a, z)$ is an entire function of z. The following properties of $\Gamma(a, z)$ hold [24, §8.4; §8.11(i)]:

$$\Gamma(a,z) = (a-1)!e^{-z} \times \sum_{k=0}^{a-1} \frac{z^k}{k!}, \text{ for } a \in \mathbb{Z}^+, z \in \mathbb{C},$$
 (D.1a)

$$\Gamma(a,z) \sim z^{a-1}e^{-z}$$
, for fixed $a \in \mathbb{C}$, as $z \to +\infty$. (D.1b)

Moreover, for real z > 0, as $z \to +\infty$ we have that [19]

$$\Gamma(z,z) = \sqrt{\frac{\pi}{2}} z^{z-\frac{1}{2}} e^{-z} + O(z^{z-1} e^{-z}),$$
(D.1c)

If $z, a \to \infty$ with $z = \lambda a$ for some $\lambda > 1$ such that $(\lambda - 1)^{-1} = o(\sqrt{|a|})$, then [19]

$$\Gamma(a,z) \sim z^a e^{-z} \times \sum_{n>0} \frac{(-a)^n b_n(\lambda)}{(z-a)^{2n+1}}.$$
 (D.1d)

The sequence $b_n(\lambda)$ satisfies the recurrence relation that $b_0(\lambda) = 1$ and 1

$$b_n(\lambda) = \lambda(1-\lambda)b'_{n-1}(\lambda) + \lambda(2n-1)b_{n-1}(\lambda), n \ge 1.$$

Proposition D.2. Let a, z, λ be positive real parameters such that $z = \lambda a$. If $\lambda \in (0,1)$, then as $z \to \infty$

$$\Gamma(a,z) = \Gamma(a) + O_{\lambda} \left(z^{a-1} e^{-z} \right).$$

If $\lambda > 1$, then as $z \to \infty$

$$\Gamma(a,z) = \frac{z^{a-1}e^{-z}}{1-\lambda^{-1}} + O_{\lambda}(z^{a-2}e^{-z}).$$

If $\lambda > 0.567142 > W(1)$ where W(x) denotes the principal branch of the Lambert W-function for $x \ge 0$, then as $z \to \infty$

$$\Gamma(a, ze^{\pm \pi i}) = -e^{\pm \pi i a} \frac{z^{a-1}e^z}{1+\lambda^{-1}} + O_{\lambda}\left(z^{a-2}e^z\right).$$

$$b_n(\lambda) = \sum_{k=0}^n \left| \left\langle n \right\rangle \right| \lambda^{k+1}.$$

¹An exact formula for $b_n(\lambda)$ is given in terms of the second-order Eulerian number triangle [27, A008517] as follows:

Note that the first two estimates are only useful when λ is bounded away from the transition point at 1. We cannot write the last expansion above as $\Gamma(a, -z)$ directly unless $a \in \mathbb{Z}^+$ as the incomplete gamma function has a branch point at the origin with respect to its second variable. This function becomes a single-valued analytic function of its second input by continuation on the universal covering of $\mathbb{C} \setminus \{0\}$.

Proof. The first asymptotic estimate follows directly from the following asymptotic series expansion that holds as $z \to +\infty$ [21, Eq. (2.1)]:

$$\Gamma(a,z) \sim \Gamma(a) + z^a e^{-z} \times \sum_{k \ge 0} \frac{(-a)^k b_k(\lambda)}{(z-a)^{2k+1}}.$$

Using the notation from (D.1d) and [20], we have that

$$\Gamma(a,z) = \frac{z^{a-1}e^{-z}}{1-\lambda^{-1}} + z^a e^{-z} R_1(a,\lambda).$$

From the bounds in $[20, \S 3.1]$, we have that

$$|z^a e^{-z} R_1(a,\lambda)| \le z^a e^{-z} \times \frac{a \cdot b_1(\lambda)}{(z-a)^3} = \frac{z^{a-2} e^{-z}}{(1-\lambda^{-1})^3}$$

The main and error terms in the previous equation can also be seen by applying the asymptotic series in (D.1d) directly.

The proof of the third equation above follows from the following asymptotics [19, Eq. (1.1)]

$$\Gamma(-a,z) \sim z^{-a} e^{-z} \times \sum_{n>0} \frac{a^n b_n(-\lambda)}{(z+a)^{2n+1}},$$

by setting $(a, z) \mapsto (ae^{\pm\pi i}, ze^{\pm\pi i})$ so that $\lambda = \frac{z}{a} > 0.567142 > W(1)$. The restriction on the range of λ over which the third formula holds is made to ensure that the last formula from the reference is valid at negative real a.

Lemma D.3. For $x \to +\infty$, we have that

$$S_1(x) := \frac{x}{\log x} \times \left| \sum_{1 \le k \le \lfloor \log \log x \rfloor} \frac{(-1)^k (\log \log x)^{k-1}}{(k-1)!} \right| = \frac{x}{2\sqrt{2\pi \log \log x}} + O\left(\frac{x}{(\log \log x)^{\frac{3}{2}}}\right).$$

Proof. We have for $n \ge 1$ and any t > 0 by (D.1a) that

$$\sum_{1 \le k \le n} \frac{(-1)^k t^{k-1}}{(k-1)!} = -e^{-t} \times \frac{\Gamma(n, -t)}{(n-1)!}.$$

Suppose that $t = n + \xi$ with $\xi = O(1)$, e.g., so we can formally take the floor of the input n to truncate the last sum. By the third formula in Proposition D.2 with the parameters $(a, z, \lambda) \mapsto (n, t, 1 + \frac{\xi}{n})$, we deduce that as $n, t \to +\infty$.

$$\Gamma(n, -t) = (-1)^{n+1} \times \frac{t^n e^t}{t+n} + O\left(\frac{nt^n e^t}{(t+n)^3}\right) = (-1)^{n+1} \frac{t^n e^t}{2n} + O\left(\frac{t^{n-1} e^t}{n}\right). \tag{D.2}$$

Accordingly, we see that

$$\sum_{1 \le k \le n} \frac{(-1)^k t^{k-1}}{(k-1)!} = (-1)^n \frac{t^n}{2n!} + O\left(\frac{t^{n-1}}{n!}\right).$$

By the variant of Stirling's formula in [24, cf. Eq. (5.11.8)], we have

$$n! = \Gamma(1+t-\xi) = \sqrt{2\pi}t^{t-\xi+\frac{1}{2}}e^{-t}\left(1+O\left(t^{-1}\right)\right) = \sqrt{2\pi}t^{n+\frac{1}{2}}e^{-t}\left(1+O\left(t^{-1}\right)\right).$$

Hence, as $n \to +\infty$ with $t := n + \xi$ and $\xi = O(1)$, we obtain that

$$\sum_{k=1}^{n} \frac{(-1)^k t^{k-1}}{(k-1)!} = (-1)^n \frac{e^t}{2\sqrt{2\pi t}} + O\left(e^t t^{-\frac{3}{2}}\right).$$

The conclusion follows by taking $n := \lfloor \log \log x \rfloor$, $t := \log \log x$ and applying the triangle inequality to obtain the result.

Definition D.4. For $x \ge 1$, let the summatory function (cf. [31])

$$L_{\omega}(x) \coloneqq \sum_{n \le x} (-1)^{\omega(n)}.$$

Lemma D.5. As $x \to \infty$, there is an absolute constant $A_0 > 0$ such that

$$L_{\omega}(x) = \frac{(-1)^{\lfloor \log \log x \rfloor} x}{A_0 \sqrt{2\pi \log \log x}} + O\left(\frac{x}{\log \log x}\right).$$

Proof. An adaptation of the proof of Lemma D.3 provides that for any $a \in (1, 1.76321) \subset (1, W(1)^{-1})$ the next partial sums satisfy

$$\widehat{S}_{a}(x) := \frac{x}{\log x} \times \left| \sum_{k=1}^{\lfloor a \log \log x \rfloor} \frac{(-1)^{k} (\log \log x)^{k-1}}{(k-1)!} \right|$$

$$= \frac{\sqrt{ax}}{\sqrt{2\pi} (a+1) a^{\{a \log \log x\}}} \times \frac{(\log x)^{a-1-a \log a}}{\sqrt{\log \log x}} \left(1 + O\left(\frac{1}{\log \log x}\right) \right). \tag{D.3}$$

Here, we take $\{x\} = x - \lfloor x \rfloor \in [0,1)$ to be the fractional part of x. Suppose that we take $a := \frac{3}{2}$ so that $a - 1 - a \log a \approx -0.108198$. We can then define and expand as

$$L_{\omega}(x) := \sum_{n \le x} (-1)^{\omega(n)} = \sum_{k \le \log \log x} 2(-1)^k \pi_k(x) + O\left(\widehat{S}_{\frac{3}{2}}(x) + \#\left\{n \le x : \omega(n) \ge \frac{3}{2} \log \log x\right\}\right).$$

The justification for the above error term including $\widehat{S}_{\frac{3}{2}}(x)$ is that for $1 \le k < \frac{3}{2} \log \log x$, we can show that $\widetilde{\mathcal{G}}\left(\frac{k-1}{\log \log x}\right) \times 1$. We apply the uniform asymptotics for $\pi_k(x)$ that hold as $x \to \infty$ when $1 \le k \le R \log \log x$ for $1 \le R < 2$ from Remark C.4. We then see by Lemma D.3 and (D.3) that for all sufficiently large x there is some absolute constant $A_0 > 0$ such that

$$L_{\omega}(x) = \frac{(-1)^{\lfloor \log \log x \rfloor} x}{A_0 \sqrt{2\pi \log \log x}} + O\left(E_{\omega}(x) + \frac{x}{(\log x)^{0.108198} \sqrt{\log \log x}} + \#\left\{n \le x : \omega(x) \ge \frac{3}{2} \log \log x\right\}\right).$$

The error term in the previous equation is bounded by the next sum as $x \to \infty$. In particular, the following estimate is obtained from Stirling's formula, and equations (D.1a) and (D.1c) from the appendix:

$$E_{\omega}(x) \ll \frac{x}{\log x} \times \sum_{1 \le k \le \log \log x} \frac{(\log \log x)^{k-2}}{(k-1)!}$$
$$= \frac{x\Gamma(\log \log x, \log \log x)}{\Gamma(\log \log x + 1)} \sim \frac{x}{2 \log \log x} \left(1 + O\left(\frac{1}{\sqrt{\log \log x}}\right)\right).$$

By an application of the second set of results in Remark C.4, we finally see that

$$\#\left\{n \le x : \omega(x) \ge \frac{3}{2}\log\log x\right\} \ll \frac{x}{(\log x)^{0.108198}}.$$

E Inversion theorems for partial sums of Dirichlet convolutions

We give a proof of the inversion type results in Theorem E.1 below by matrix methods in this subsection. Related results on summations of Dirichlet convolutions and their inversion appear in [1, §2.14; §3.10; §3.12; cf. §4.9, p. 95].

Theorem E.1 (Partial sums of Dirichlet convolutions and their inversions). Let $r, h : \mathbb{Z}^+ \to \mathbb{C}$ be any arithmetic functions such that $r(1) \neq 0$. Suppose that $R(x) := \sum_{n \leq x} r(n)$ and $H(x) := \sum_{n \leq x} h(n)$ denote the summatory functions of r and h, respectively, and that $R^{-1}(x) := \sum_{n \leq x} r^{-1}(n)$ denotes the summatory function of the Dirichlet inverse of r for any $x \geq 1$. For any $x \geq 1$, let the partial sums of the Dirichlet convolution r * h be defined by

$$S_{r*h}(x) \coloneqq \sum_{n \le x} \sum_{d|n} r(d) h\left(\frac{n}{d}\right).$$

We have that the following exact expressions hold for all integers $x \ge 1$:

$$S_{r*h}(x) = \sum_{d=1}^{x} r(d)H\left(\left\lfloor \frac{x}{d} \right\rfloor\right)$$
$$S_{r*h}(x) = \sum_{k=1}^{x} H(k)\left(R\left(\left\lfloor \frac{x}{k} \right\rfloor\right) - R\left(\left\lfloor \frac{x}{k+1} \right\rfloor\right)\right).$$

Moreover, for any $x \ge 1$ we have

$$H(x) = \sum_{j=1}^{x} S_{r*h}(j) \left(R^{-1} \left(\left\lfloor \frac{x}{j} \right\rfloor \right) - R^{-1} \left(\left\lfloor \frac{x}{j+1} \right\rfloor \right) \right)$$
$$= \sum_{k=1}^{x} r^{-1}(k) S_{r*h}(x).$$

Proof of Theorem E.1. Let h, r be arithmetic functions such that $r(1) \neq 0$. We let $S_f(x)$ denote the partial sums of the function f over $n \leq x$. The following formulas hold for all $x \geq 1$:

$$S_{r*h}(x) := \sum_{n=1}^{x} \sum_{d|n} r(n)h\left(\frac{n}{d}\right) = \sum_{d=1}^{x} r(d)H\left(\left\lfloor \frac{x}{d}\right\rfloor\right)$$
$$= \sum_{i=1}^{x} \left(R\left(\left\lfloor \frac{x}{i}\right\rfloor\right) - R\left(\left\lfloor \frac{x}{i+1}\right\rfloor\right)\right)H(i). \tag{E.1}$$

The first formula on the right-hand-side above is well known from the references. The second formula is justified directly using summation by parts as [24, §2.10(ii)]

$$S_{r*h}(x) = \sum_{d=1}^{x} h(d)R\left(\left\lfloor \frac{x}{d} \right\rfloor\right)$$
$$= \sum_{i \le x} \left(\sum_{j \le i} h(j)\right) \times \left(R\left(\left\lfloor \frac{x}{i} \right\rfloor\right) - R\left(\left\lfloor \frac{x}{i+1} \right\rfloor\right)\right).$$

We form the invertible matrix of coefficients, denoted by \hat{R} below, associated with the linear system defining H(j) for all $1 \le j \le x$ in (E.1) by setting

$$r_{x,j} \coloneqq R\left(\left\lfloor\frac{x}{j}\right\rfloor\right) - R\left(\left\lfloor\frac{x}{j+1}\right\rfloor\right) \equiv R_{x,j} - R_{x,j+1},$$

with

$$R_{x,j} := R\left(\left\lfloor \frac{x}{j} \right\rfloor\right), \text{ for } 1 \le j \le x.$$

Since $r_{x,x} = R(1) = r(1) \neq 0$ for all $x \geq 1$ and $r_{x,j} = 0$ for all j > x, the matrix we have defined in this problem is lower triangular with a non-zero constant on its diagonals, and so is invertible. If we let $\hat{R} := (R_{x,j})$, then the next matrix is expressed by applying an invertible shift operation as

$$(r_{x,j}) = \hat{R}(I - U^T).$$

The square matrix U of sufficiently large finite dimensions $N \times N$ for $N \ge x$ has $(i,j)^{th}$ entries for all $1 \le i,j \le N$ that are defined by $(U)_{i,j} = \delta_{i+1,j}$ so that

$$\left[\left(I-U^T\right)^{-1}\right]_{i,j}=\left[j\leq i\right]_{\delta}.$$

We observe that

$$\left\lfloor \frac{x}{j} \right\rfloor - \left\lfloor \frac{x-1}{j} \right\rfloor = \begin{cases} 1, & \text{if } j | x; \\ 0, & \text{otherwise.} \end{cases}$$

The previous equation implies that

$$R\left(\left\lfloor \frac{x}{j}\right\rfloor\right) - R\left(\left\lfloor \frac{x-1}{j}\right\rfloor\right) = \begin{cases} r\left(\frac{x}{j}\right), & \text{if } j|x; \\ 0, & \text{otherwise.} \end{cases}$$
 (E.2)

We use the property in (E.2) to shift the matrix \hat{R} , and then invert the result to obtain a matrix involving the Dirichlet inverse of r as follows:

$$\left(\left(I - U^T\right)\hat{R}\right)^{-1} = \left(r\left(\frac{x}{j}\right)[j|x]_{\delta}\right)^{-1} = \left(r^{-1}\left(\frac{x}{j}\right)[j|x]_{\delta}\right).$$

Our target matrix in the inversion problem is defined by

$$(r_{x,j}) = (I - U^T) \left(r \left(\frac{x}{j} \right) [j|x]_{\delta} \right) (I - U^T)^{-1}.$$

We can express its inverse by a similarity transformation conjugated by shift operators in the form of

$$(r_{x,j})^{-1} = (I - U^T)^{-1} \left(r^{-1} \left(\frac{x}{j} \right) [j|x]_{\delta} \right) (I - U^T)$$

$$= \left(\sum_{k=1}^{\left\lfloor \frac{x}{j} \right\rfloor} r^{-1}(k) \right) (I - U^T)$$

$$= \left(\sum_{k=1}^{\left\lfloor \frac{x}{j} \right\rfloor} r^{-1}(k) - \sum_{k=1}^{\left\lfloor \frac{x}{j+1} \right\rfloor} r^{-1}(k) \right).$$

The summatory function H(x) is given exactly for any integers $x \ge 1$ by a vector product with the inverse matrix from the previous equation in the form of

$$H(x) = \sum_{k=1}^{x} \left(\sum_{j=\left\lfloor \frac{x}{k+1} \right\rfloor + 1}^{\left\lfloor \frac{x}{k} \right\rfloor} r^{-1}(j) \right) \times S_{r * h}(k).$$

We can prove a second inversion formula providing the coefficients of the summatory function $R^{-1}(j)$ for $1 \le j \le x$ from the last equation by adapting our argument to prove (E.1) above. This leads to the alternate identity expressing H(x) given by

$$H(x) = \sum_{k=1}^{x} r^{-1}(k) \times S_{r*h}\left(\left\lfloor \frac{x}{k} \right\rfloor\right).$$

Table F: Computations involving $g(n) \equiv (\omega + 1)^{-1}(n)$ and G(x) for $1 \le n \le 500$.

- ▶ The column labeled Primes provides the prime factorization of each n so that the values of $\omega(n)$ and $\Omega(n)$ are easily extracted. The columns labeled Sqfree and PPower, respectively, list inclusion of n in the sets of squarefree integers and the prime powers.
- The next three columns provide the explicit values of the inverse function g(n) and compare its explicit value with other estimates. We define the function f₁(n) := ∑_{k=0}^{ω(n)} (^{ω(n)}_k) × k!.
 The last columns indicate properties of the summatory function of g(n). The notation for the (approximate)
- The last columns indicate properties of the summatory function of g(n). The notation for the (approximate) densities of the sign weight of g(n) is defined as $\mathcal{L}_{\pm}(x) := \frac{1}{n} \times \# \{n \le x : \lambda(n) = \pm 1\}$. The last three columns then show the sign weighted components to the signed summatory function, $G(x) := \sum_{n \le x} g(n)$, decomposed into its respective positive and negative magnitude sum contributions: $G(x) = G_{+}(x) + G_{-}(x)$ where $G_{+}(x) > 0$ and $G_{-}(x) < 0$ for all $x \ge 1$. That is, the component functions $G_{\pm}(x)$ displayed in these second to last two columns of the table correspond to the summatory function G(x) with summands that are positive and negative, respectively. The final column of the table provides the partial sums of the absolute value of the unsigned inverse sequence, $|G|(n) := \sum_{k \le n} |g(k)|$.
