Math proof that should be a good short read

Dear Professor,

Greetings and happy Sunday.

I have a new (pre)preprint draft of some work I've been doing recently to extend the results in: <https://arxiv.org/abs/2102.05842>. The original article is actually a really, really excellent and promising manuscript that got dropped finishing my PhD at Georgia Tech because the faculty that would even claim enough expertise in the area to review it are (pardon for being blunt) glorified idiots with fancy titles and (go figure) tenure. These new results based on the arXiv preprint use probabilistic number theory to simplify several key sums that provide exact formulas for $M(x)$, or as you well remember publishing about, the partial sums of the classical Moebius function. The hypotheses assumed are reasonable and can be made rigorous via other methods. The new sums resulting from these formulas lead me to prove a well-known classical conjecture about the unboundedness of $M(x)/\sqrt{x}$ along large, infinite increasing subsequences of the positive integers.

The thing is that no one I know in the math world really wants to touch this topic. And I'm a little nervous to show it to other mathematicians right away or just blindly submit the article for review without feedback because of what a big deal this proof panning out will mean. I need some basic feedback on it nonetheless. The new manuscript is short at about 9 pages + references. The summary of past results is a little dense, but the key ideas I used to compute limiting asymptotic lower bounds on the scaled Mertens function are not technical. Will you take 30-60 minutes (say) to give me your impressions of these new results? It will really help me gather my thoughts, gain more confidence about the proof method, and would be a huge, very much appreciated professional favor in this otherwise dreary year in the era of Donald Trump. You will get to be one of the first creative souls to read through an article that may very well prove a breakthrough result on a function that mathematicians have been studying now for more than 200-250 years.

Please email me back about this when you have some free time. I will send you the new short article at that point. I'm looking forward to getting iTn touch with you again this year.

Thank you. Take care,

Dr. Maxie Dion Schmidt

Dear Maxie

I am sorry you feel people have been unfair and uninterested, but hopefully you can get Ernie to give you a fair response? There is also a new prof in analytic number theory at Ga Tech, Alex Dunn, who might know quite a bit about this topic. You could also try Paul Pollack at UGa (who is a very empathetic kind of guy)

I am currently running a large research program at U de M with 35 or so people in residence and am barely keeping my head above water as it is, so I cannot commit to looking at your stuff till this is over and I have had a long vacation! Better to try people at Ga Tech and/or UGa

Good luck

Andrew G

Hello again,

You were one of the few souls I asked to help review the paper who actually had the decency to give a response back - no, and that's okay. Because I respect that, I wanted to send you the following:

I submitted the preprint to arXiv. Usually when I post a manuscript there, they tell me it will be published in a few days before which I can make small revisions. This time, they sent a different message saying that they need 2+ business days to review/referee the article to make sure it is reasonable enough to be in their archive. It passes basic scrutiny so that there are not any obvious or easy to pick out glaring errors as it stands:

<http://arxiv.org/abs/2604.23517>

As far as going through GT number theory faculty for the paper, you really will not get what you're asking me to compromise if I had to do that. The story is long, too long for email, and not my prerogative to blast for academic purposes. No one else will say that, it is what it is in fact, and maybe it's best to drop it for this message.

Kind regards to the respectable gentleman. Sincerely,

Dr. Maxie Dion Schmidt
